An Introduction to Convolutional Neural Networks

Yuan YAO

HKUST

Summary

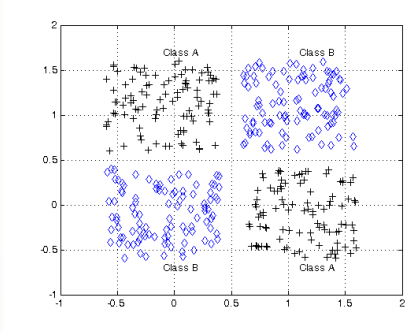
- We had covered so far
  - Linear models (linear and logistic regression) – always a good start, simple yet powerful
  - Model Assessment and Selection – basics for all methods
  - Trees, Random Forests, and Boosting – good for high dim mixed-type heterogeneous features
  - Support Vector Machines – good for small amount of data but high dim geometric features
- Next, neural networks for unstructured data (image, language etc.):
  - **Convolutional Neural Networks** – image data
  - Recurrent Neural Networks, LSTM – sequence data
  - Transformer, BERT – machine translation etc.
  - Generative models and GANs – new unsupervised learning for image, etc.
  - Reinforcement Learning – Markov decision process, playing games, etc.

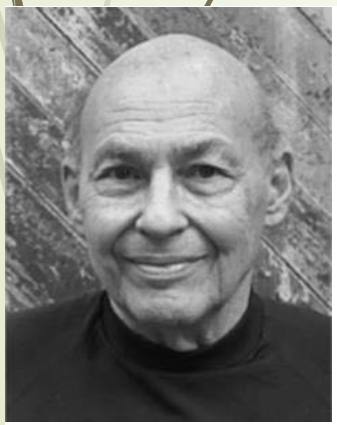
Locality or Sparsity of Computation

Minsky and Papert, 1969

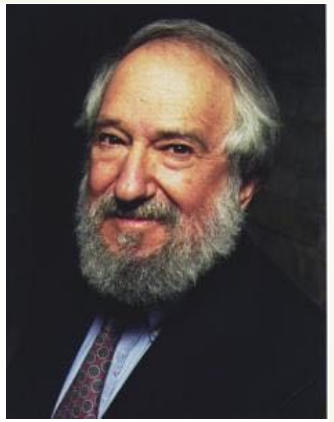
Perceptron can't do **XOR** classification

Perceptron needs infinite global information to compute **connectivity**





Marvin Minsky

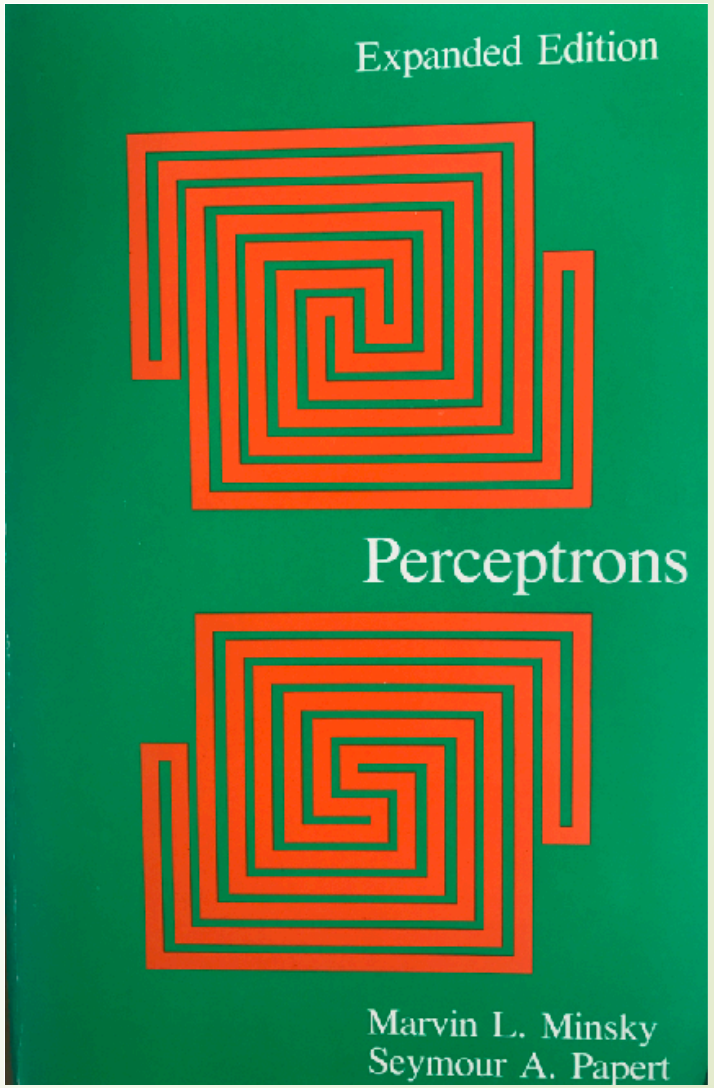


Seymour Papert

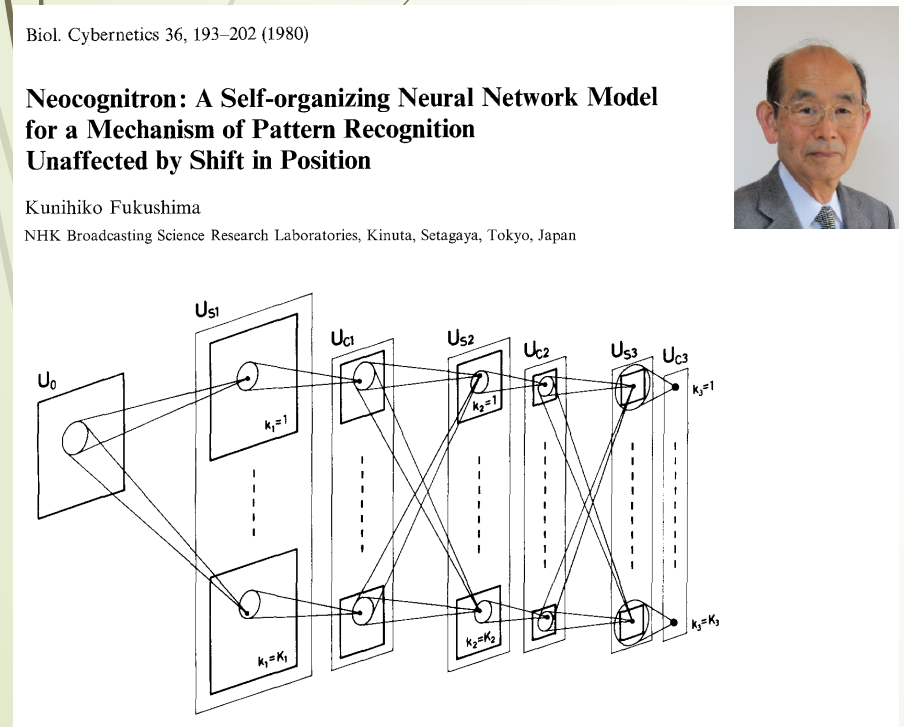
Locality or **Sparsity** is important:

Locality in time?

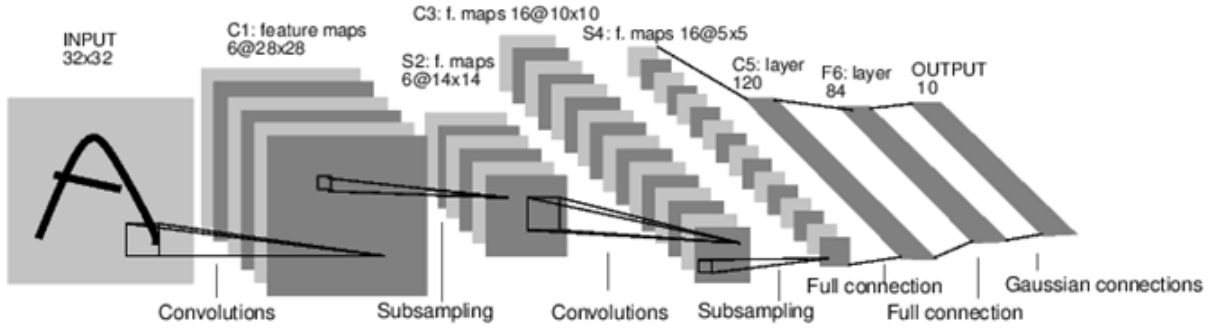
Locality in space?



Convolutional Neural Networks: shift invariances and locality for images



- Can be traced to *Neocognitron* of Kunihiko Fukushima (1979)
- Yann LeCun combined convolutional neural networks with back propagation (1989)
- Imposes **shift invariance** and **locality** on the weights
- Forward pass remains similar
- Backpropagation slightly changes – need to sum over the gradients from all spatial positions

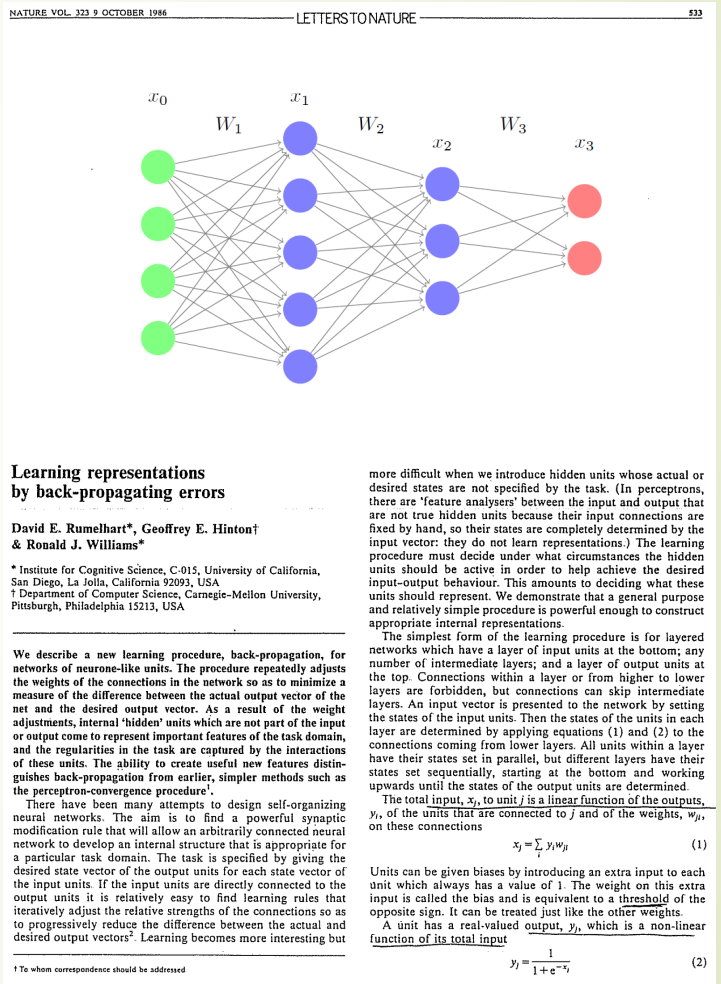


Multilayer Perceptrons (MLP) and Back-Propagation (BP) Algorithms

Rumelhart, Hinton, Williams (1986)
Learning representations by back-propagating errors, Nature, 323(9): 533-536

BP algorithms as **stochastic gradient descent** algorithms (**Robbins–Monro 1950; Kiefer-Wolfowitz 1951**) with Chain rules of Gradient maps

MLP classifies **XOR**, but the global hurdle on topology (connectivity) computation still exists



NATURE VOL. 323 9 OCTOBER 1986 — LETTERS TO NATURE — 533

Learning representations by back-propagating errors

David E. Rumelhart*, Geoffrey E. Hinton† & Ronald J. Williams*

* Institute for Cognitive Science, C-015, University of California, San Diego, La Jolla, California 92093, USA
† Department of Computer Science, Carnegie-Mellon University, Pittsburgh, Philadelphia 15213, USA

We describe a new learning procedure, back-propagation, for networks of neurone-like units. The procedure repeatedly adjusts the weights of the connections in the network so as to minimize a measure of the difference between the actual output vector of the net and the desired output vector. As a result of the weight adjustments, internal 'hidden' units which are not part of the input or output come to represent important features of the task domain, and the regularities in the task are captured by the interactions of these units. The ability to create useful new features distinguishes back-propagation from earlier, simpler methods such as the perceptron-convergence procedure[1].

There have been many attempts to design self-organizing neural networks. The aim is to find a powerful synaptic modification rule that will allow an arbitrarily connected neural network to develop an internal structure that is appropriate for a particular task domain. The task is specified by giving the desired state vector of the output units for each state vector of the input units. If the input units are directly connected to the output units it is relatively easy to find learning rules that iteratively adjust the relative strengths of the connections so as to progressively reduce the difference between the actual and desired output vectors[2]. Learning becomes more interesting but more difficult when we introduce hidden units whose actual or desired states are not specified by the task. (In perceptrons, there are 'feature analysers' between the input and output that are not true hidden units because their input connections are fixed by hand, so their states are completely determined by the input vector: they do not learn representations.) The learning procedure must decide under what circumstances the hidden units should be active in order to help achieve the desired input-output behaviour. This amounts to deciding what these units should represent. We demonstrate that a general purpose and relatively simple procedure is powerful enough to construct appropriate internal representations.

The simplest form of the learning procedure is for layered networks which have a layer of input units at the bottom; any number of intermediate layers; and a layer of output units at the top. Connections within a layer or from higher to lower layers are forbidden, but connections can skip intermediate layers. An input vector is presented to the network by setting the states of the input units. Then the states of the units in each layer are determined by applying equations (1) and (2) to the connections coming from lower layers. All units within a layer have their states set in parallel, but different layers have their states set sequentially, starting at the bottom and working upwards until the states of the output units are determined.

The total input, x_j, to unit j is a linear function of the outputs, y_i, of the units that are connected to j and of the weights, w_{ji}, on these connections

$$x_j = \sum_i y_i w_{ji} \quad (1)$$

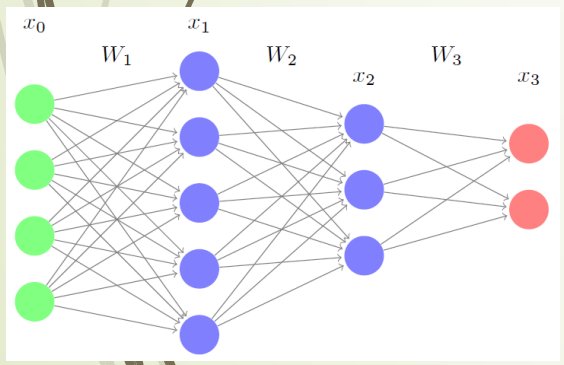
Units can be given biases by introducing an extra input to each unit which always has a value of 1. The weight on this extra input is called the bias and is equivalent to a threshold of the opposite sign. It can be treated just like the other weights.

A unit has a real-valued output, y_j, which is a non-linear function of its total input

$$y_j = \frac{1}{1+e^{-x_j}} \quad (2)$$

† To whom correspondence should be addressed

BP Algorithm: Forward Pass



- Cascade of repeated [linear operation followed by coordinatewise nonlinearity]'s
- Nonlinearities: sigmoid, hyperbolic tangent, (recently) ReLU.

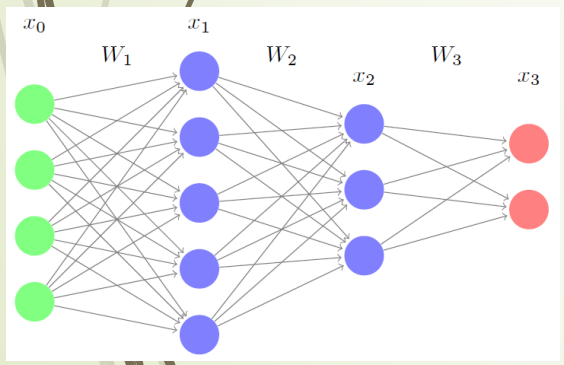
Algorithm 1 Forward pass

Input: x_0

Output: x_L

1: **for** $\ell = 1$ to L **do**
2: $\quad x_\ell = f_\ell(W_\ell x_{\ell-1} + b_\ell)$
3: **end for**

BP algorithm = Gradient Descent Method



- Training examples $\{x_0^i\}_{i=1}^n$ and labels $\{y^i\}_{i=1}^n$
- Output of the network $\{x_L^i\}_{i=1}^m$
- Objective

$$J(\{W_l\},\{b_l\}) = \frac{1}{n}\sum_{i=1}^{n}\frac{1}{2}\|y^i - x_L^i\|_2^2 \qquad (1)$$

Other losses include cross-entropy, logistic loss, exponential loss, etc.

- Gradient descent

$$W_l = W_l - \eta\frac{\partial J}{\partial W_l}$$

$$b_l = b_l - \eta\frac{\partial J}{\partial b_l}$$

In practice: use Stochastic Gradient Descent (SGD)

Derivation of BP: Lagrangian Multiplier

LeCun et al. 1988

Given n training examples $(I_i, y_i) \equiv$ (input,target) and L layers

- Constrained optimization

$$\begin{aligned} \min_{W,x} \quad & \textstyle\sum_{i=1}^{n} \|x_i(L) - y_i\|_2 \\ \text{subject to} \quad & x_i(\ell) = f_\ell\Big[W_\ell x_i\,(\ell-1)\Big], \\ & i = 1, \ldots, n, \quad \ell = 1, \ldots, L,\ x_i(0) = I_i \end{aligned}$$

- Lagrangian formulation (Unconstrained)

$$\min_{W,x,B} \mathcal{L}(W, x, B)$$

$$\mathcal{L}(W, x, B) = \textstyle\sum_{i=1}^{n} \left\{ \|x_i(L) - y_i\|_2^2 + \right.$$

$$\left. \textstyle\sum_{\ell=1}^{L} B_i(\ell)^T \left(x_i(\ell) - f_\ell\Big[W_\ell x_i\,(\ell-1)\Big] \right) \right\}$$

http://yann.lecun.com/exdb/publis/pdf/lecun-88.pdf

back-propagation – derivation

- $\frac{\partial \mathcal{L}}{\partial B}$

Forward pass

$$x_i(\ell) = f_\ell\Big[\underbrace{W_\ell x_i\,(\ell-1)}_{A_i(\ell)}\Big] \quad \ell = 1,\ldots,L, \quad i = 1,\ldots,n$$

- $\frac{\partial \mathcal{L}}{\partial x}, z_\ell = [\nabla f_\ell] B(\ell)$

Backward (adjoint) pass

$$z(L) = 2\nabla f_L\Big[A_i(L)\Big]\,(y_i - x_i(L))$$

$$z_i(\ell) = \nabla f_\ell\Big[A_i(\ell)\Big] W_{\ell+1}^T z_i(\ell+1) \quad \ell = 0,\ldots,L-1$$

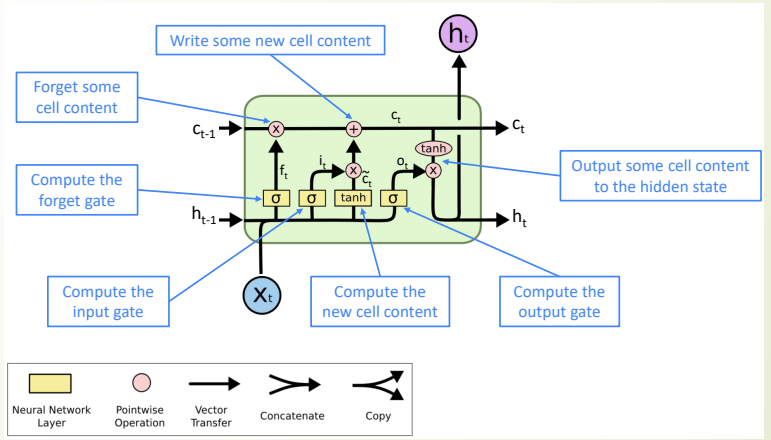
- $W \leftarrow W + \lambda \frac{\partial \mathcal{L}}{\partial W}$

Weight update

$$W_\ell \leftarrow W_\ell + \lambda \sum_{i=1}^n z_i(\ell) x_i^T(\ell-1)$$

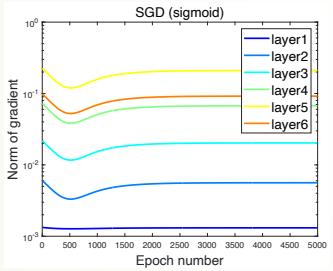
Long-Short-Term-Memory (LSTM, 1997)

- Sepp Hochreiter; Jürgen Schmidhuber (1997). "Long short-term memory". *Neural Computation*. **9** (8): 1735–1780. (https://www.bioinf.jku.at/publications/older/2604.pdf)
- BP can not train deep networks due to gradient vanishing problem etc.
- Introduction of **short path** to train deep networks without vanishing gradient problem.
- This idea will come back to Convolutional Networks as **ResNet** in 2015.

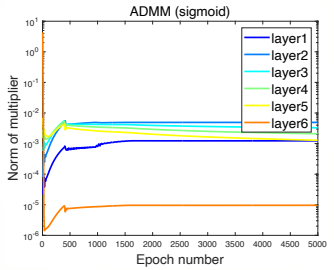


SGD vs. ADMM/BCD

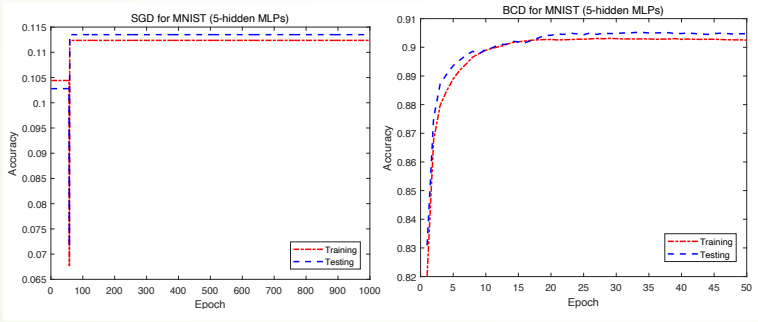
- Stochastic Gradient Descent (SGD) suffers from the well-known *gradient vanishing issue* in deep learning
- ADMM/BCD may alleviate gradient vanishing

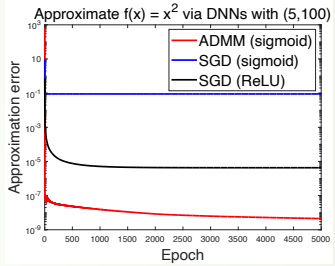


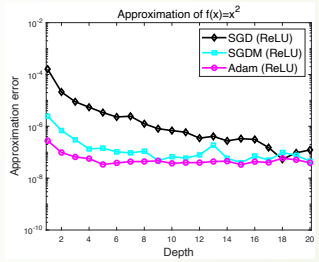
(a) Gradient vanishing of SGD



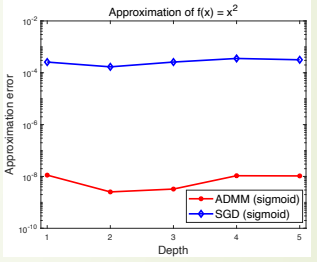
(b) Saturation-avoidance of ADMM





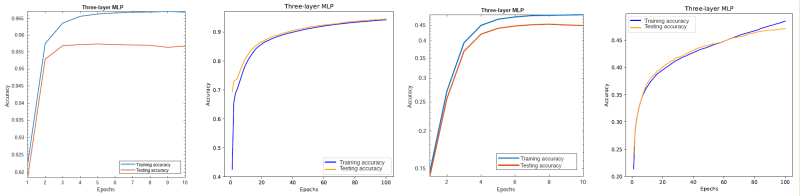


(a) Deep ReLU nets



(b) Deep sigmoid nets

- High epoch efficiency of BCD at early stage



(a) MNIST (BCD) (b) MNIST (SGD) (c) CIFAR-10 (BCD) (d) CIFAR-10 (SGD)

Zeng-Lau-Lin-Y., ICML 2019
Zeng-Lin-Y.-Zhou, JMLR 2021

Notes on Algorithms

- Gradient descent (back propagation) can be derived via Lagrangian multiplier method [LeCun 1988, http://yann.lecun.com/exdb/publis/pdf/lecun-88.pdf]
- **ADMM** is alternative primal-dual method via **Augmented Lagrangian** multipliers [Zeng-Lin-Y.-Zhou, JMLR 2021]
- **BCD** (Block-Coordinate-Descent) ***drops*** the dual update in Augmented Lagrangian multipliers [Zeng-Lau-Lin-Y., ICML 2019]
- *Global convergence to KKT points from arbitrary initialization* can be established with the aid of ***Kurdyka-Łojasiewicz*** framework.

$$\underset{\mathcal{W},\mathcal{V}}{\text{minimize}} \ \frac{1}{2}\|V_N - Y\|_F^2 + \frac{\lambda}{2}\sum_{i=1}^{N}\|W_i\|_F^2$$

$$\text{subject to} \quad V_i = \sigma(W_i V_{i-1}),\ i = 1, \ldots, N-1, \quad V_N = W_N V_{N-1},$$

Augmented Lagrangian function:

$$\mathcal{L}(\mathcal{W}, \mathcal{V}, \{\Lambda_i\}_{i=1}^N) := \frac{1}{2}\|V_N - Y\|_F^2 + \frac{\lambda}{2}\sum_{i=1}^{N}\|W_i\|_F^2$$
$$+ \sum_{i=1}^{N-1}\left(\frac{\beta_i}{2}\|\sigma(W_i V_{i-1}) - V_i\|_F^2 + \langle \Lambda_i, \sigma(W_i V_{i-1}) - V_i\rangle\right)$$
$$+ \frac{\beta_N}{2}\|W_N V_{N-1} - V_N\|_F^2 + \langle \Lambda_N, W_N V_{N-1} - V_N\rangle,$$

Lagrangian multiplier Λ_i

Support Vector Machine (Max-Margin Classifier)

$$\text{minimize}_{\beta_0,\beta_1,\ldots,\beta_p} \|\beta\|^2 := \sum_j \beta_j^2$$

$$\text{subject to } y_i(\beta_0 + \beta_1 x_{i1} + \ldots + \beta_p x_{ip}) \geq 1 \text{ for all } i$$

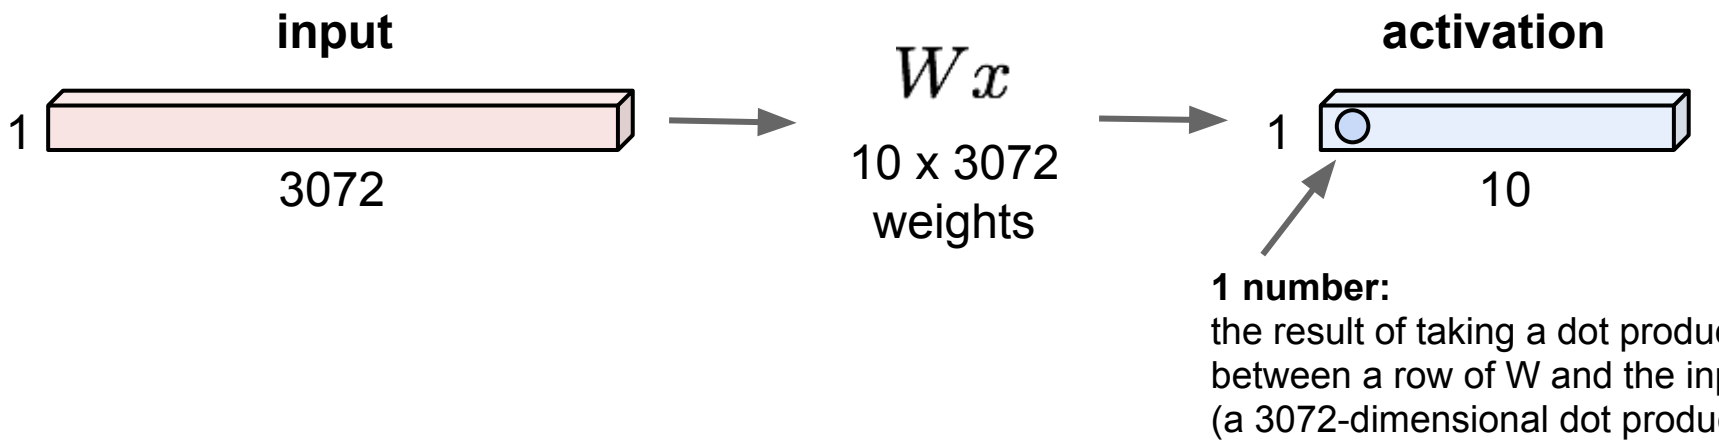
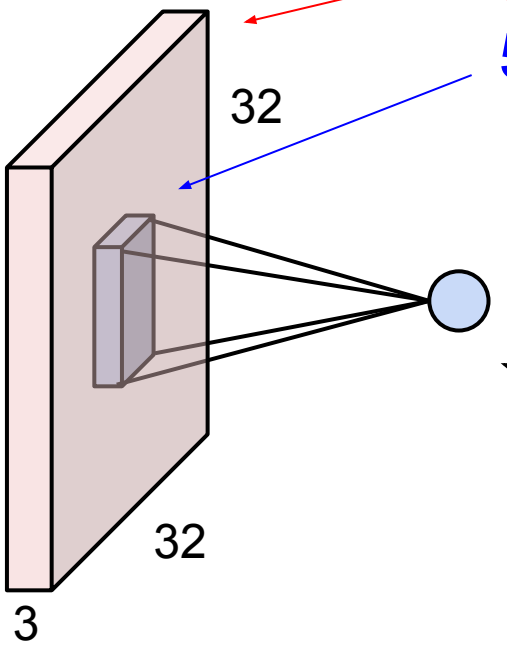
Fully Connected Layer

32x32x3 image -> stretch to 3072 x 1



Convolution



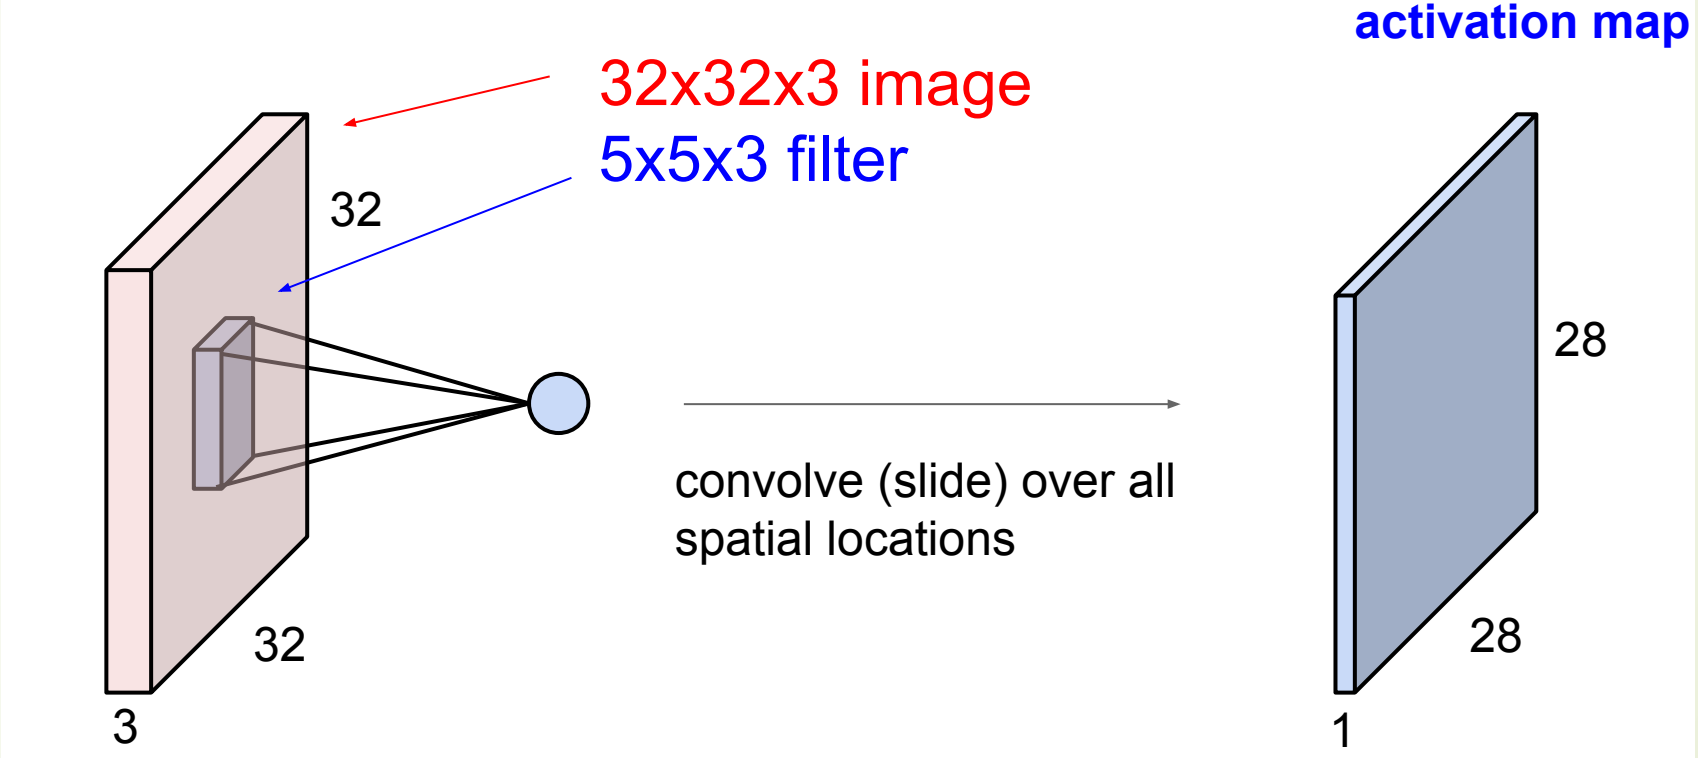
32x32x3 image

5x5x3 filter w

1 number:
the result of taking a dot product between the filter and a small 5x5x3 chunk of the image
(i.e. 5*5*3 = 75-dimensional dot product + bias)

$$w^T x + b$$

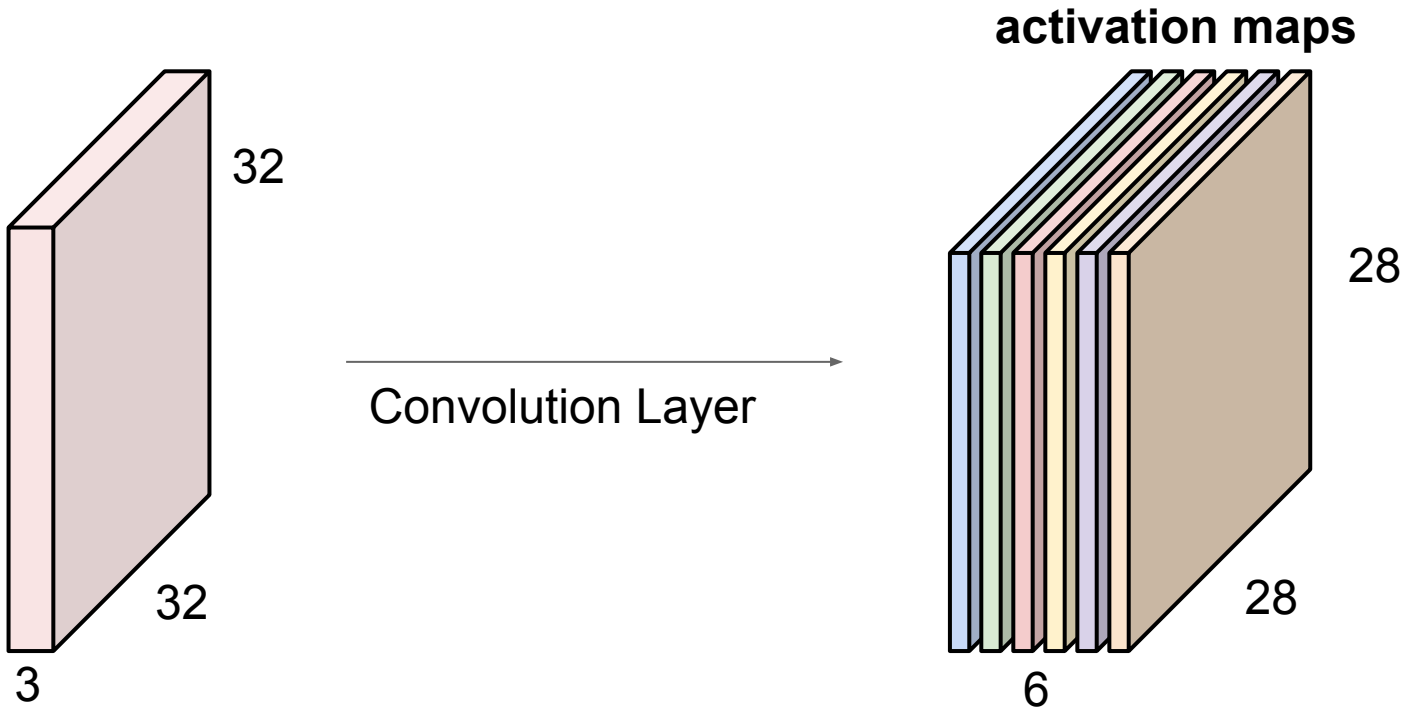
Convolution Layer: a first (blue) filter



Convolution Layer: a second (green) filter

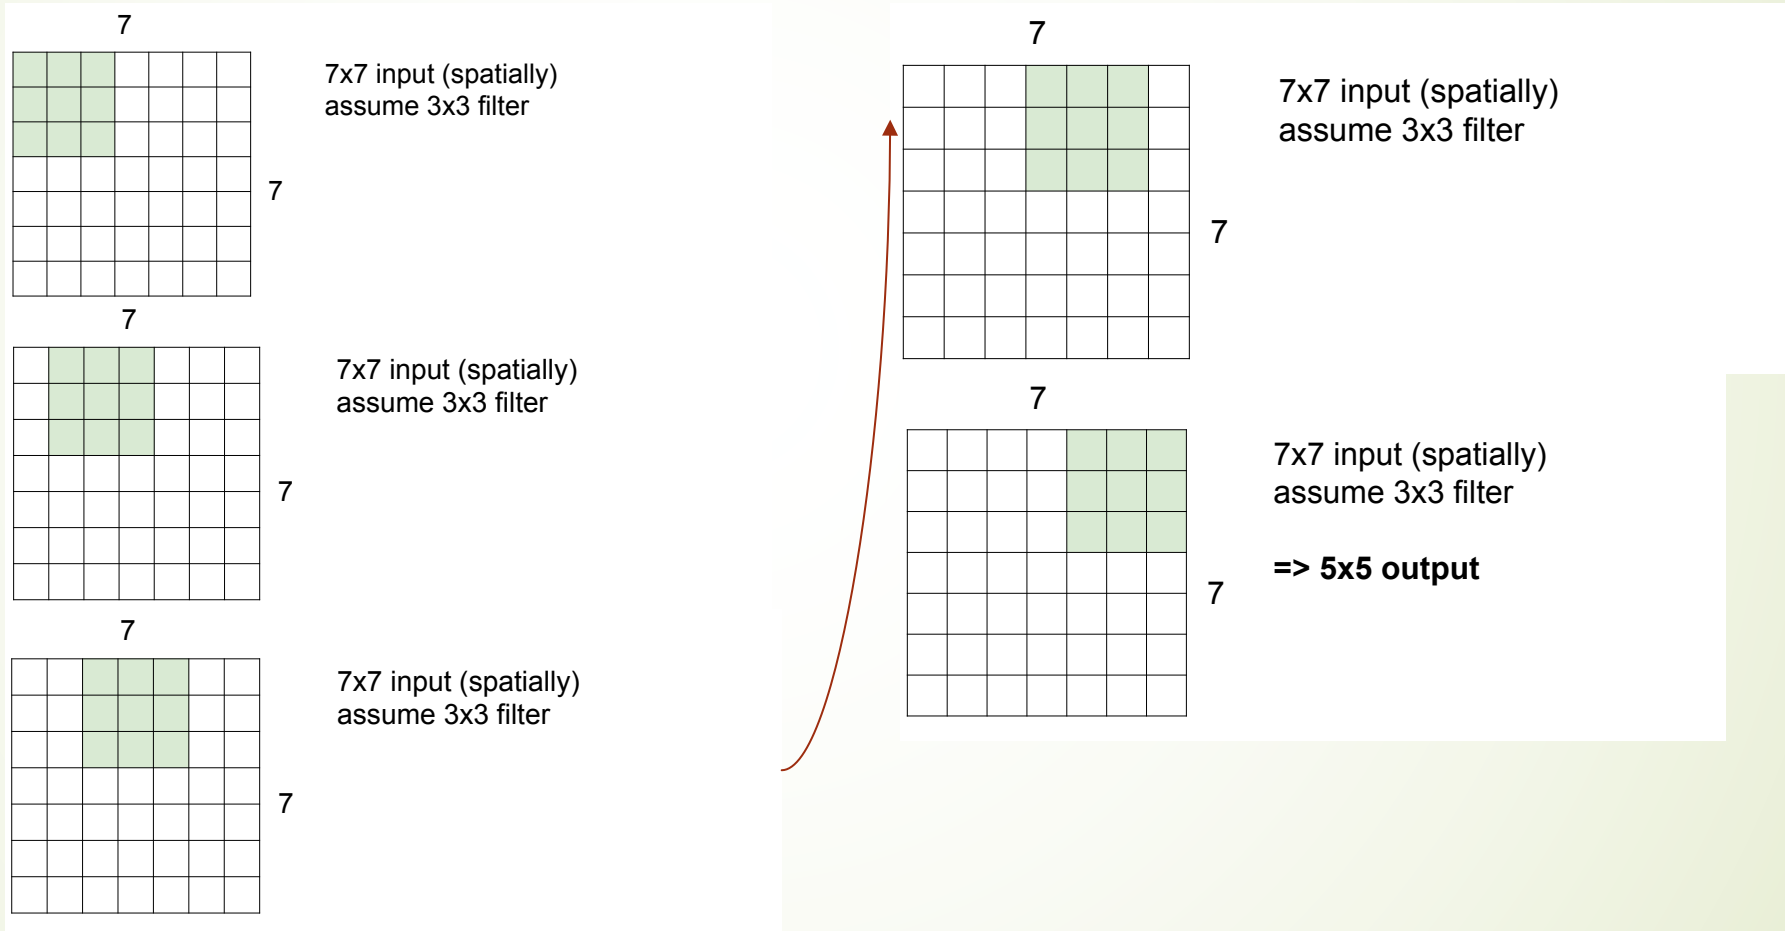
Convolution Layer

For example, if we had 6 5x5 filters, we'll get 6 separate activation maps:

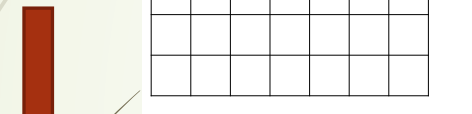


We stack these up to get a "new image" of size 28x28x6!

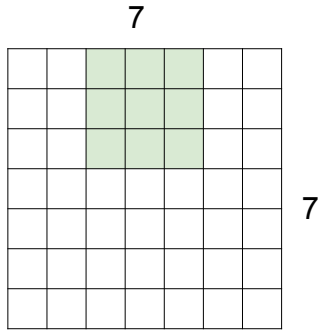
A Closer Look at Convolution: stride=1



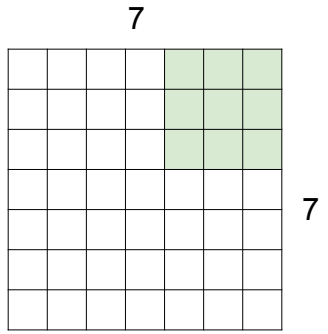
A Closer Look at Convolution: stride=2



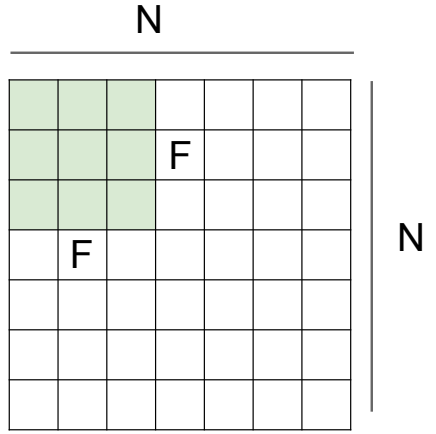
7x7 input (spatially)
assume 3x3 filter
applied **with stride 2**



7x7 input (spatially)
assume 3x3 filter
applied **with stride 2**



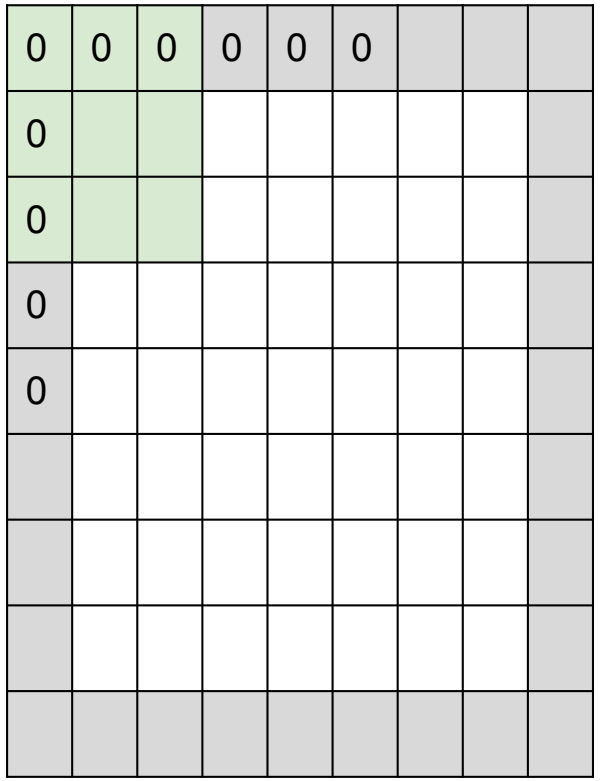
7x7 input (spatially)
assume 3x3 filter
applied **with stride 2**
=> 3x3 output!



Output size:
(N - F) / stride + 1

e.g. N = 7, F = 3:
stride 1 => (7 - 3)/1 + 1 = 5
stride 2 => (7 - 3)/2 + 1 = 3
stride 3 => (7 - 3)/3 + 1 = 2.33 :\

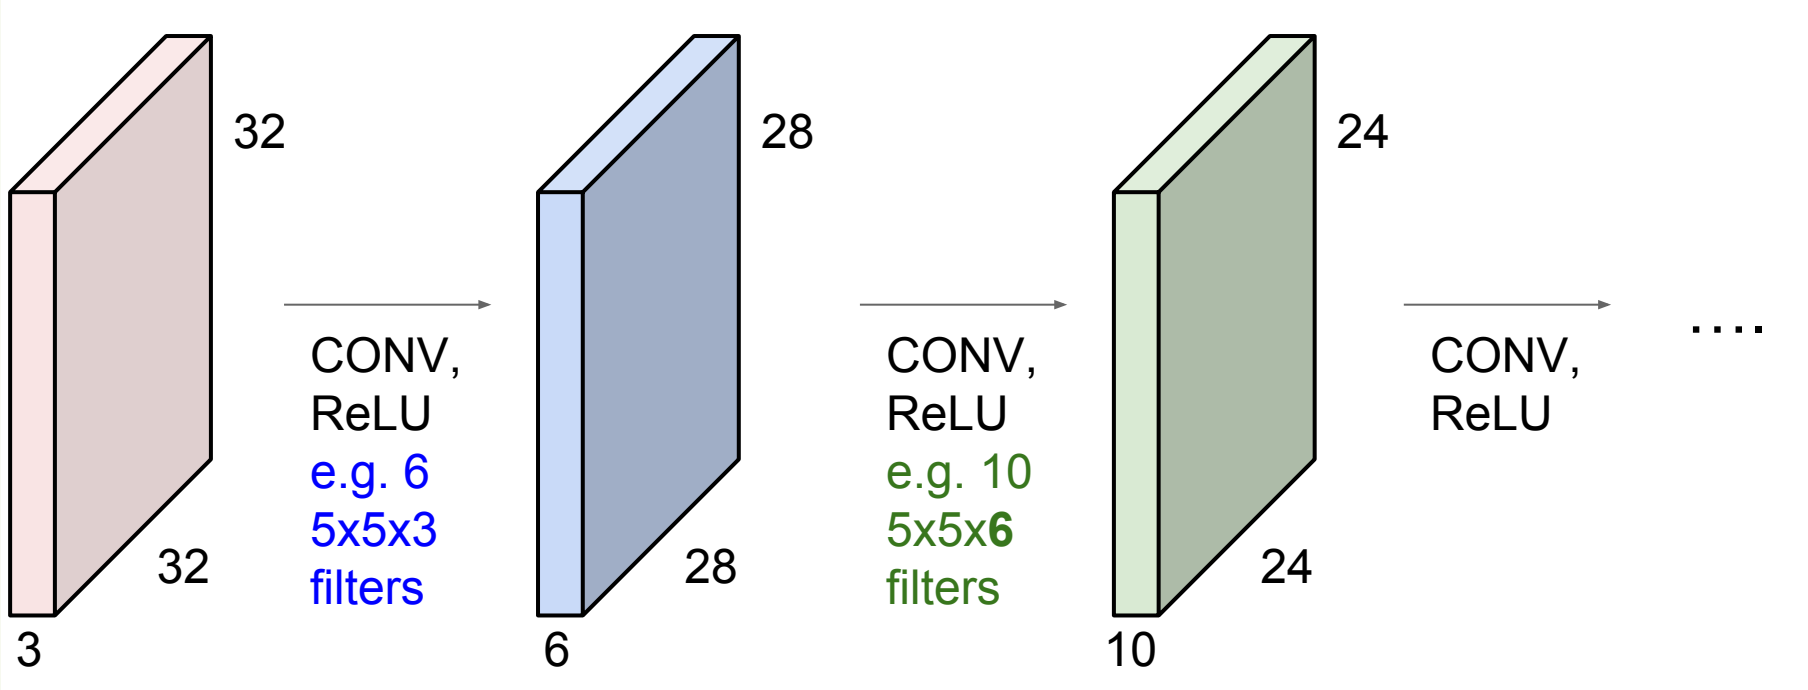
A Closer Look at Convolution: Padding



e.g. input 7x7
3x3 filter, applied with **stride 1**
pad with 1 pixel border => what is the output?

7x7 output!
in general, common to see CONV layers with stride 1, filters of size FxF, and zero-padding with (F-1)/2. (will preserve size spatially)
e.g. F = 3 => zero pad with 1
F = 5 => zero pad with 2
F = 7 => zero pad with 3

ConvNet:



Stride = 1
Padding = 0

Formula: NewImageSize = floor((ImageSize – Filter + 2*Padding)/Stride + 1)

Summary. To summarize, the Conv Layer:

- Accepts a volume of size $W_1 \times H_1 \times D_1$
- Requires four hyperparameters:
  - Number of filters K,
  - their spatial extent F,
  - the stride S,
  - the amount of zero padding P.
- Produces a volume of size $W_2 \times H_2 \times D_2$ where:
  - $W_2 = (W_1 - F + 2P)/S + 1$
  - $H_2 = (H_1 - F + 2P)/S + 1$ (i.e. width and height are computed equally by symmetry)
  - $D_2 = K$
- With parameter sharing, it introduces $F \cdot F \cdot D_1$ weights per filter, for a total of $(F \cdot F \cdot D_1) \cdot K$ weights and K biases.
- In the output volume, the d-th depth slice (of size $W_2 \times H_2$) is the result of performing a valid convolution of the d-th filter over the input volume with a stride of S, and then offset by d-th bias.

ReLU

- Non-saturating function and therefore faster convergence when compared to other nonlinearities
- Problem of dying neurons

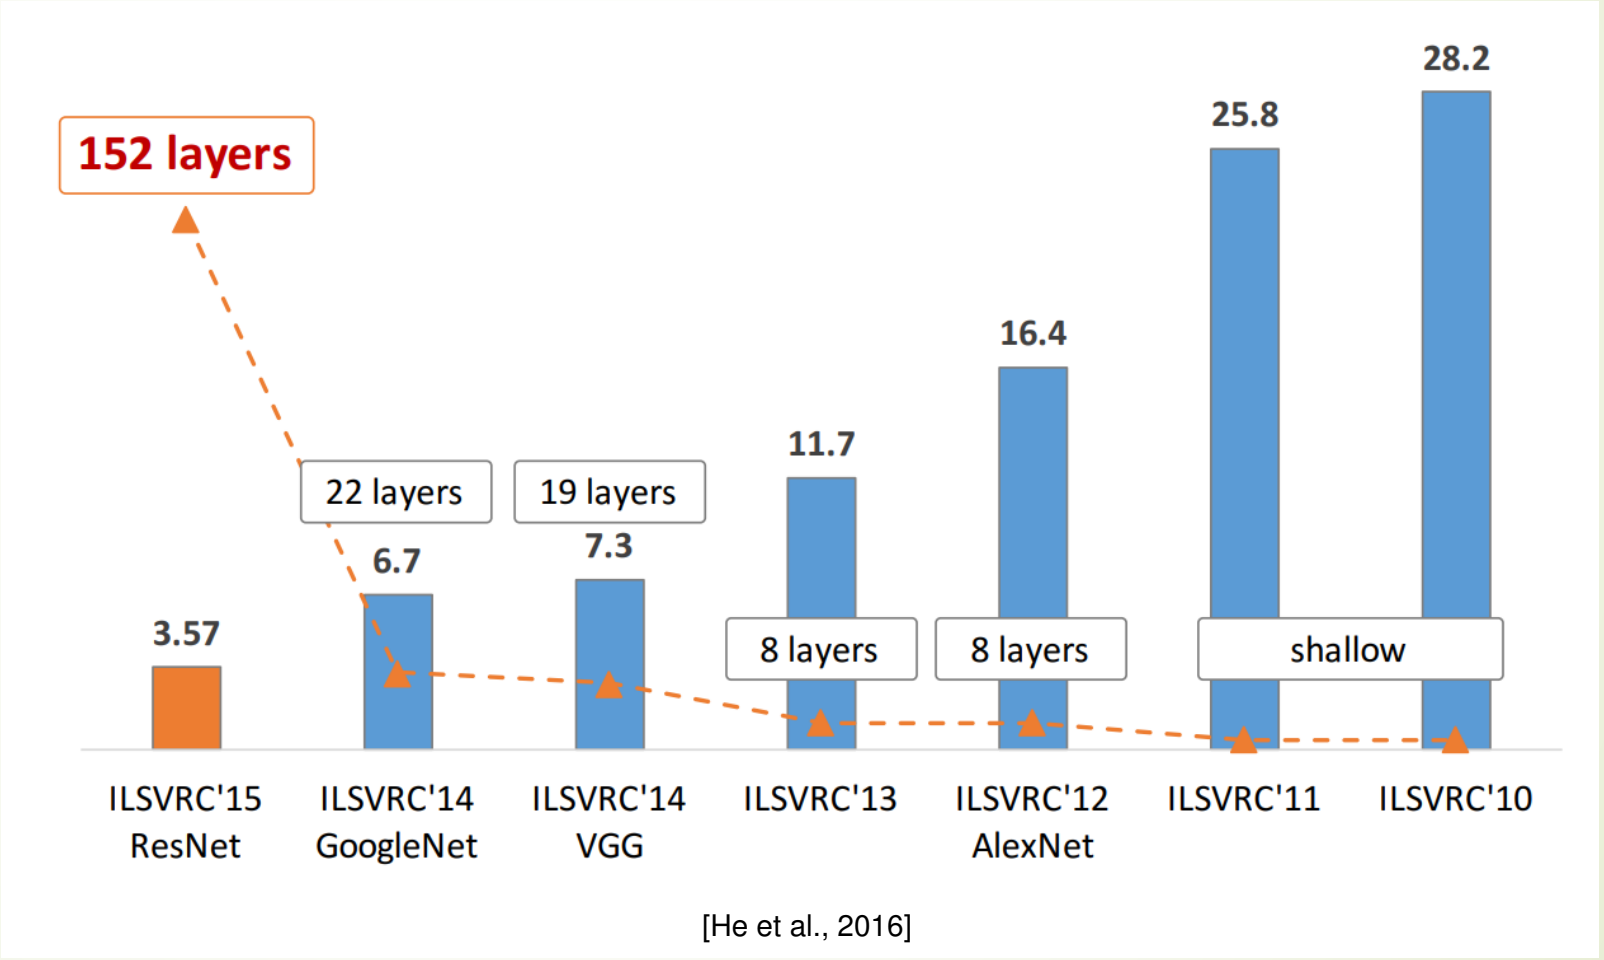
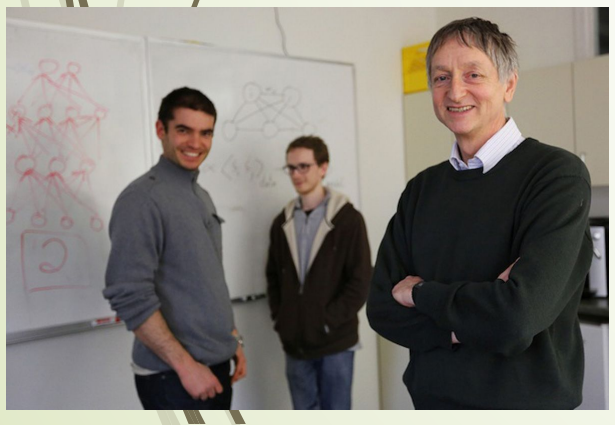
Deep Learning

Depth as function of year

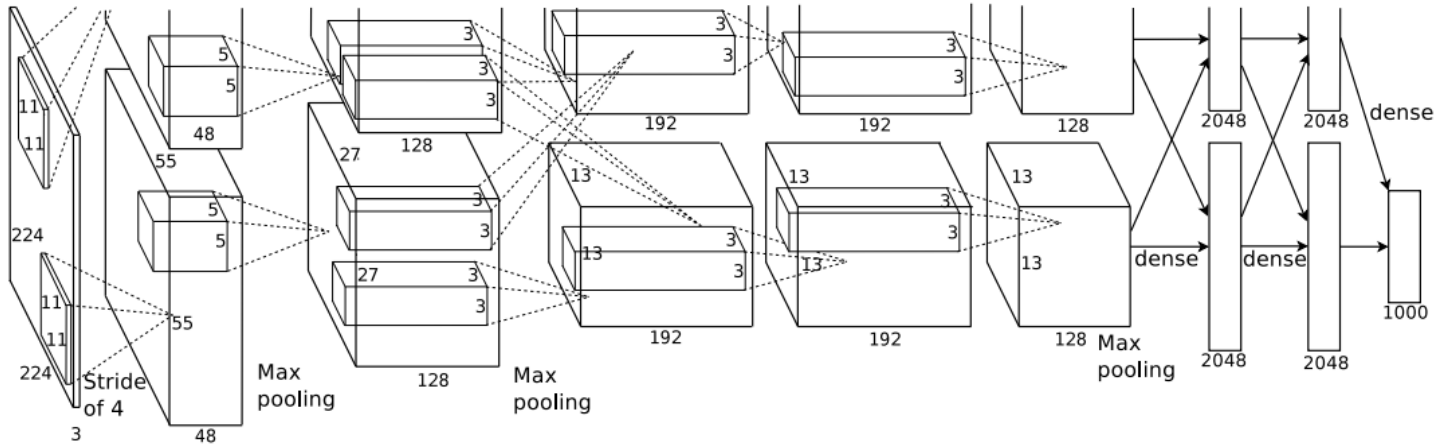


[He et al., 2016]

AlexNet (2012): Architecture

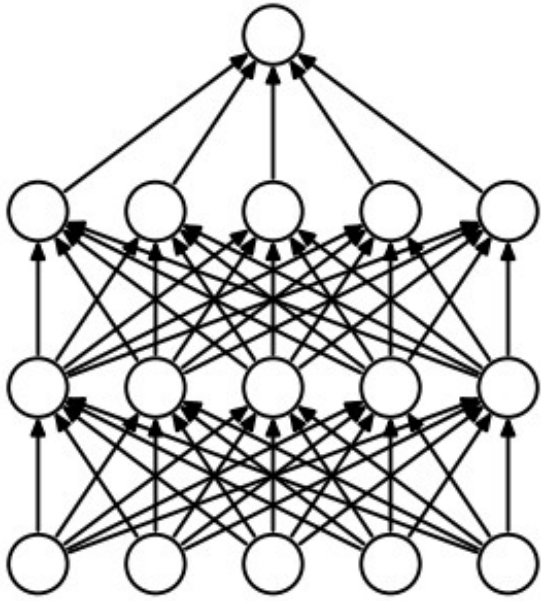


- 8 layers: first 5 convolutional, rest fully connected
- ReLU nonlinearity
- Local response normalization
- Max-pooling
- Dropout

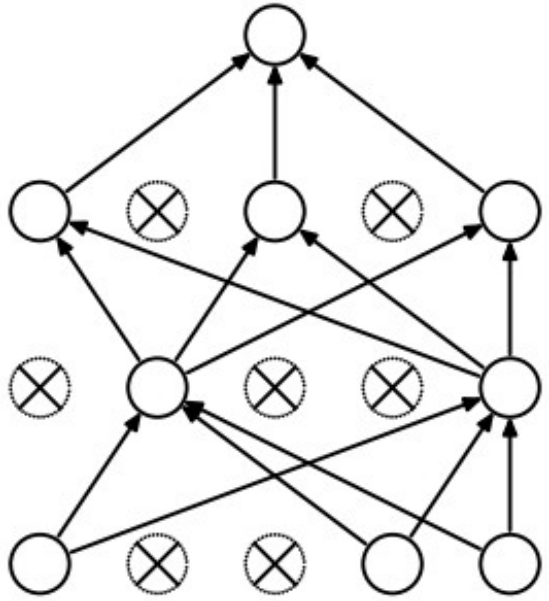


Source: [Krizhevsky et al., 2012]

AlexNet (2012): Dropout



(a) Standard Neural Net



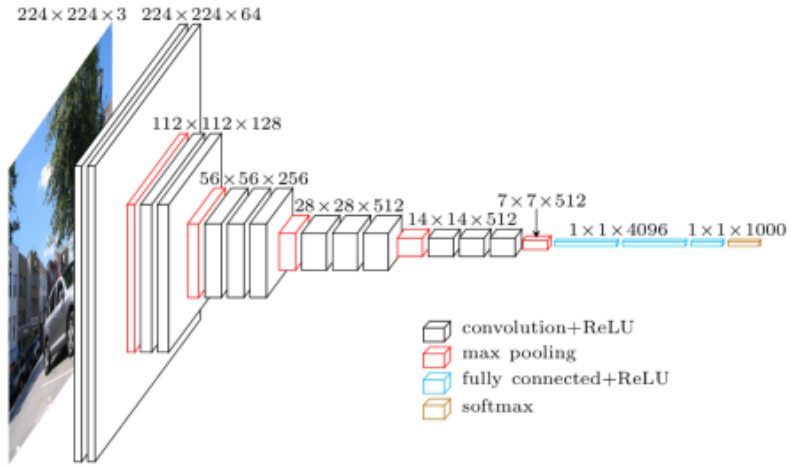
(b) After applying dropout.

Source: [Srivastava et al., 2014]

- Zero every neuron with probability $1 - p$
- At test time, multiply every neuron by p

VGG (2014) [Simonyan-Zisserman'14]

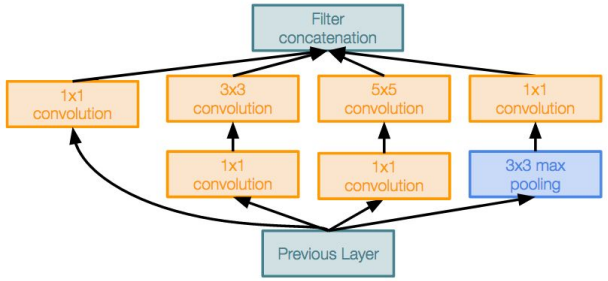
- Deeper than AlexNet: 11-19 layers versus 8
- No local response normalization
- Number of filters multiplied by two every few layers
- Spatial extent of filters 3×3 in all layers
- Instead of 7×7 filters, use three layers of 3×3 filters
  - Gain intermediate nonlinearity
  - Impose a regularization on the 7×7 filters



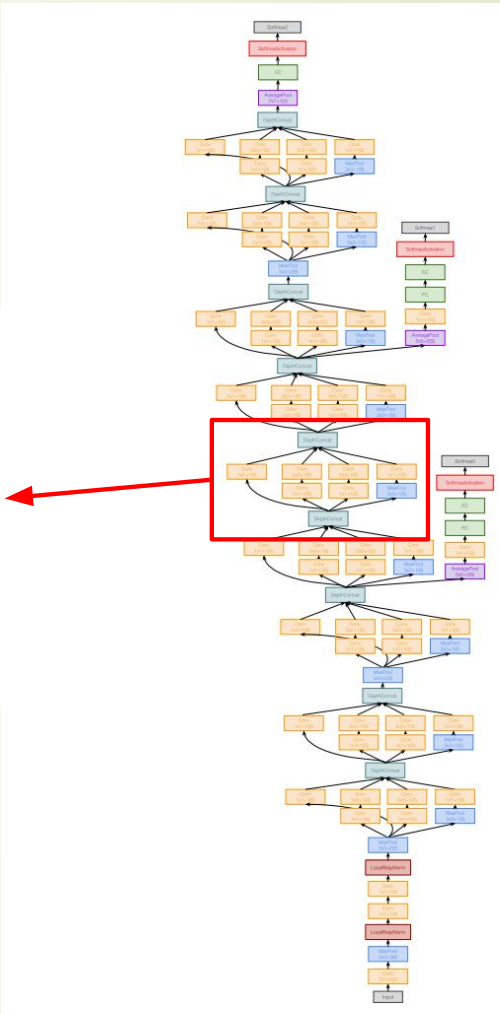
Source: https://blog.heuritech.com/2016/02/29/

GoogLeNet *[Szegedy et al., 2014]*

- 22 layers
- Efficient "Inception" module
- No FC layers
- Only 5 million parameters!
- 12x less than AlexNet
- ILSVRC'14 classification winner (6.7% top 5 error)

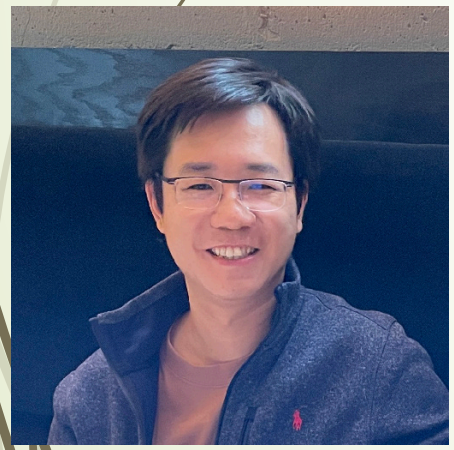


Inception module

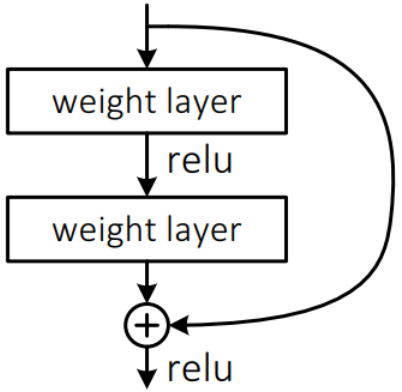


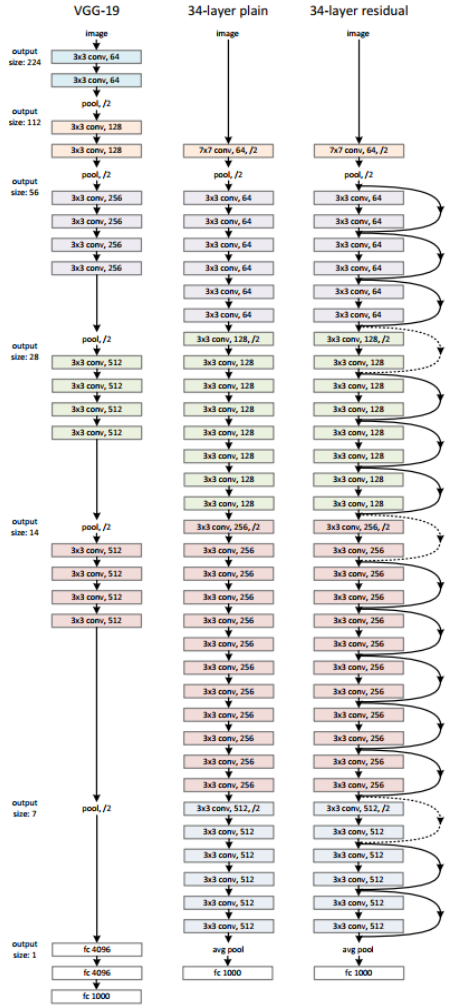
ResNet (2015) [HGRS-15]

ILSVRC'15 classification winner (3.57% top 5 error)



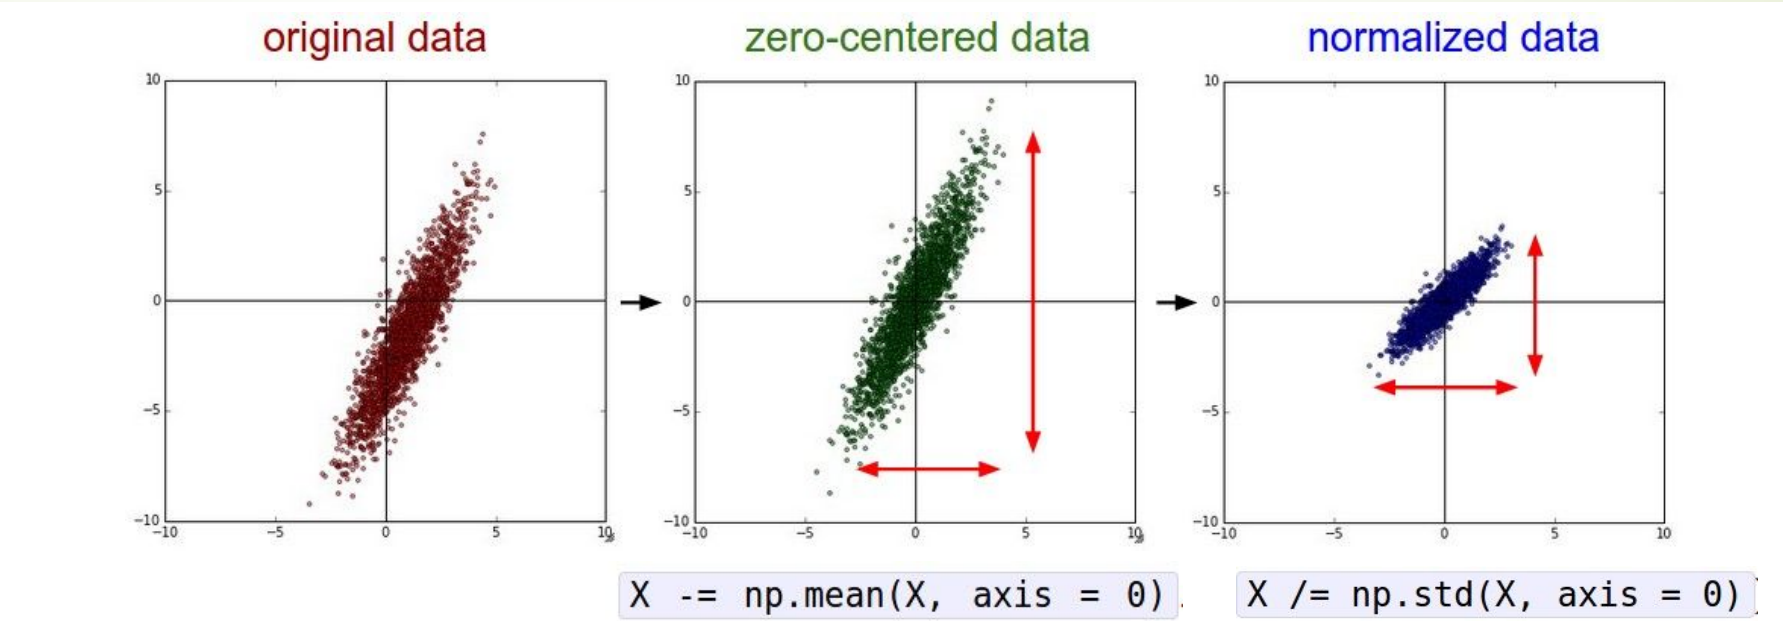
- Solves problem by adding skip connections
- Very deep: 152 layers
- No dropout
- Stride
- Batch normalization





Source: Deep Residual Learning for Image Recognition

Batch Normalization



(Assume X [NxD] is data matrix,
each example in a row)

Batch Normalization

Algorithm 2 Batch normalization [Ioffe and Szegedy, 2015]

Input: Values of x over minibatch $x_1 \dots x_B$, where x is a certain channel in a certain feature vector

Output: Normalized, scaled and shifted values $y_1 \dots y_B$

1: $\mu = \frac{1}{B} \sum_{b=1}^{B} x_b$

2: $\sigma^2 = \frac{1}{B} \sum_{b=1}^{B} (x_b - \mu)^2$

3: $\hat{x}_b = \frac{x_b - \mu}{\sqrt{\sigma^2 + \epsilon}}$

4: $y_b = \gamma \hat{x}_b + \beta$

- Accelerates training and makes initialization less sensitive
- Zero mean and unit variance feature vectors

BatchNorm at Test

Input: Values of x over a mini-batch: $\mathcal{B} = \{x_{1...m}\}$;
Parameters to be learned: γ, β

Output: $\{y_i = \mathrm{BN}_{\gamma,\beta}(x_i)\}$

$$\mu_{\mathcal{B}} \leftarrow \frac{1}{m}\sum_{i=1}^{m} x_i \qquad \text{// mini-batch mean}$$

$$\sigma^2_{\mathcal{B}} \leftarrow \frac{1}{m}\sum_{i=1}^{m}(x_i - \mu_{\mathcal{B}})^2 \qquad \text{// mini-batch variance}$$

$$\widehat{x}_i \leftarrow \frac{x_i - \mu_{\mathcal{B}}}{\sqrt{\sigma^2_{\mathcal{B}} + \epsilon}} \qquad \text{// normalize}$$

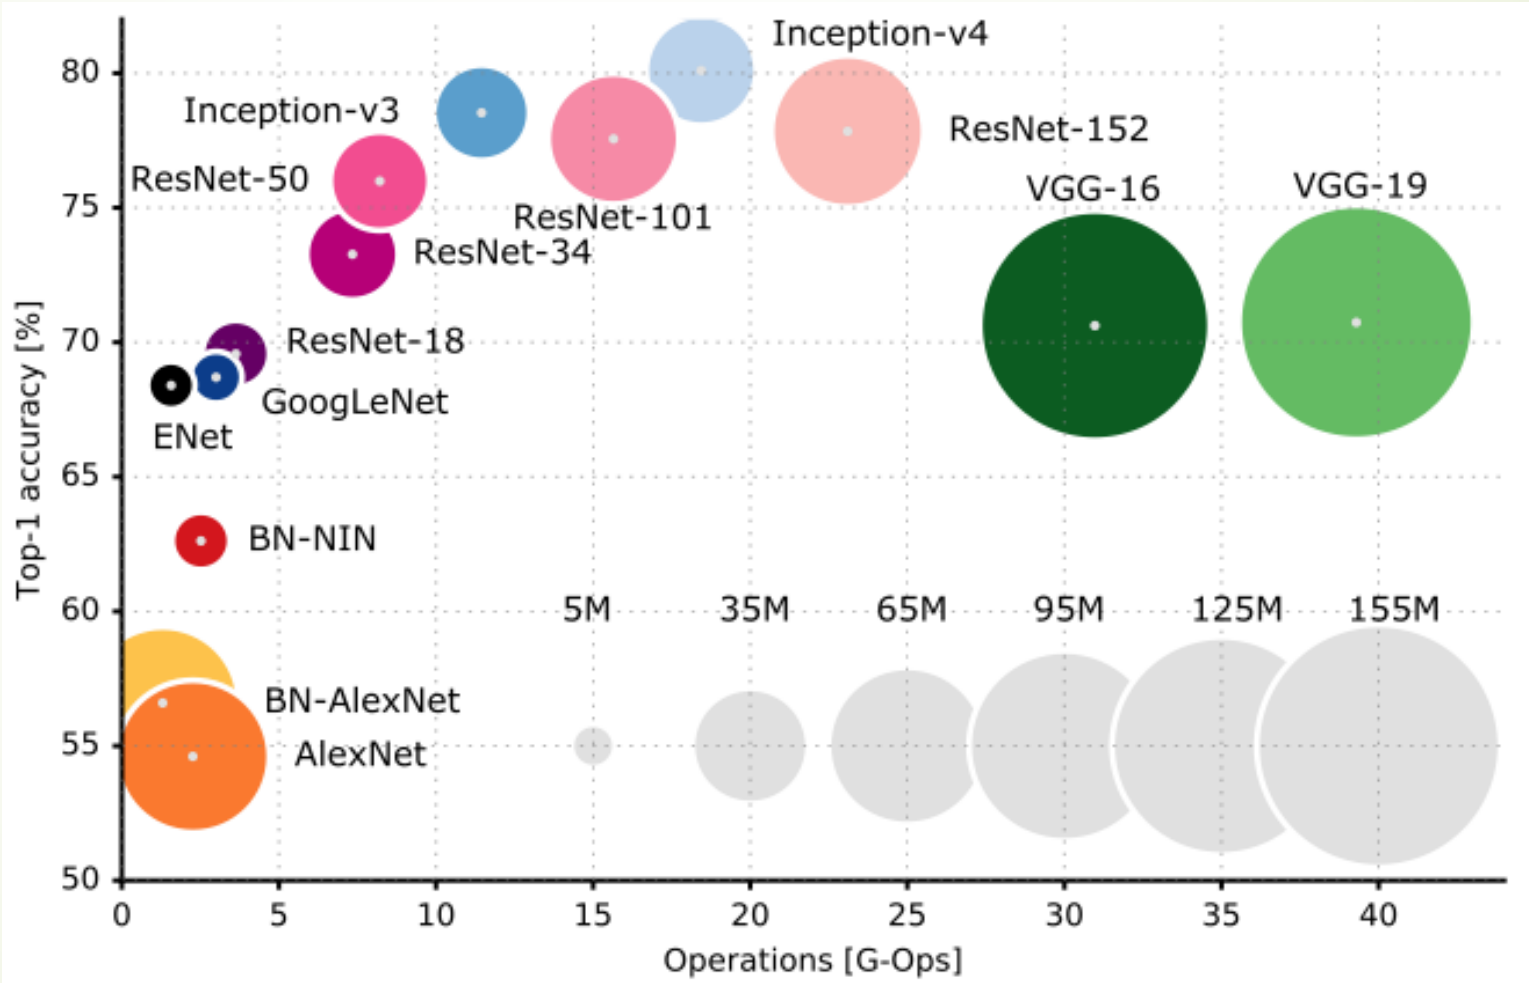
$$y_i \leftarrow \gamma\widehat{x}_i + \beta \equiv \mathrm{BN}_{\gamma,\beta}(x_i) \qquad \text{// scale and shift}$$

Note: at test time BatchNorm layer functions differently:

The mean/std are not computed based on the batch. Instead, a single fixed empirical mean of activations during training is used.

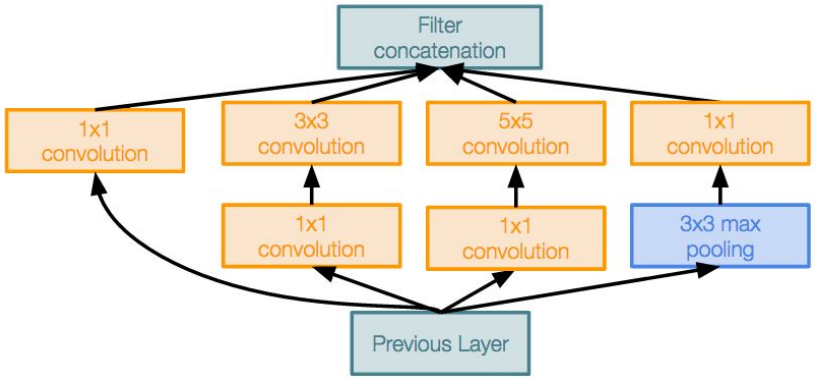
(e.g. can be estimated during training with running averages)

Complexity vs. Accuracy of Different Networks

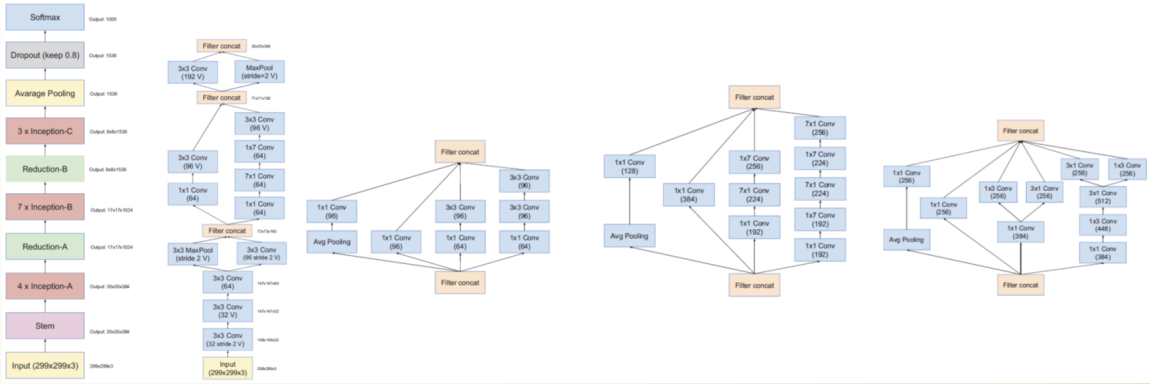


Inception-v4 = ResNet + Inception

- "**Inception**" module:
  - Introduced by *Szegedy et al., 2014* in ***GoogLeNet***
  - ILSVRC'14 classification winner (6.7% top 5 error)
- Apply parallel filter operations on the input from previous layer:
  - Dimensionality reduction (1x1 conv)
  - Multiple receptive field sizes for convolution (1x1, 3x3, 5x5)
  - Pooling operation (3x3)
- Concatenate all filter outputs together depth-wise



Inception module



Deep Learning Softwares

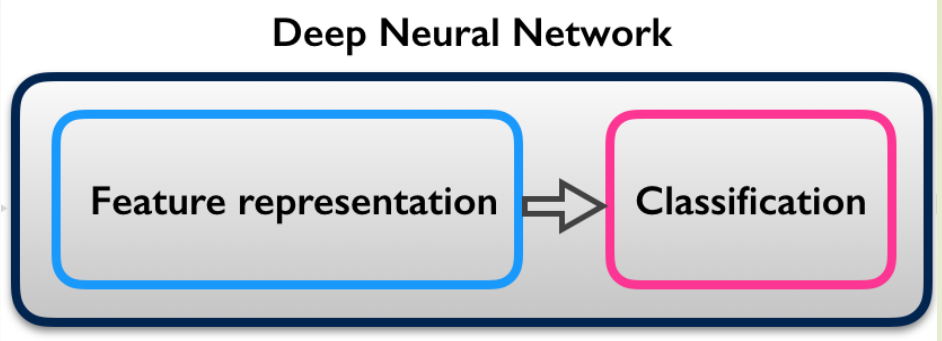
Transfer Learning:
Feature Extraction and Fine Tuning

Transfer Learning?

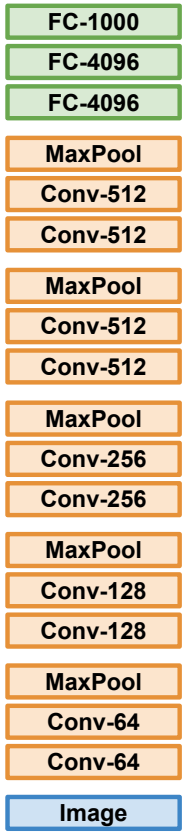


- Filters learned in first layers of a network are transferable from one task to another
- When solving another problem, no need to retrain the lower layers, just fine tune upper ones
- Is this simply due to the large amount of images in ImageNet?
- Does solving many classification problems simultaneously result in features that are more easily transferable?
- Does this imply filters can be learned in unsupervised manner?
- Can we characterize filters mathematically?

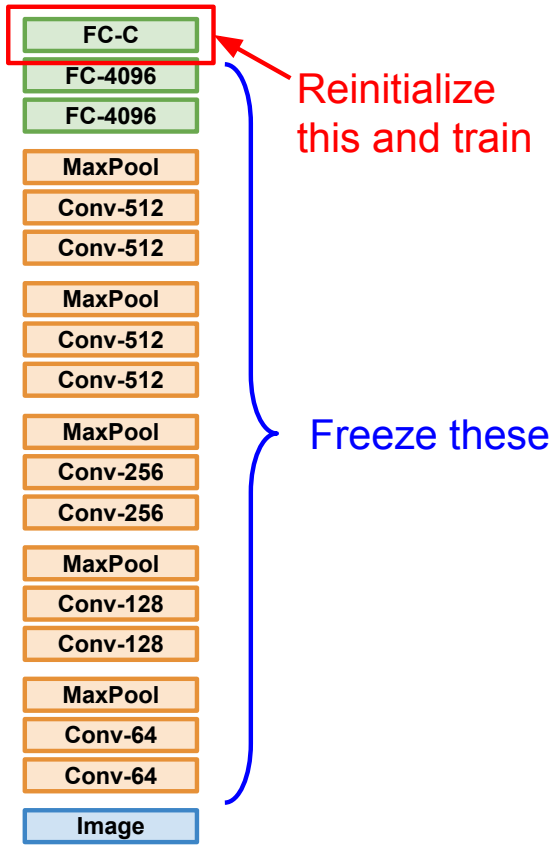
Transfer Learning with CNNs

Donahue et al, "DeCAF: A Deep Convolutional Activation Feature for Generic Visual Recognition", ICML 2014
Razavian et al, "CNN Features Off-the-Shelf: An Astounding Baseline for Recognition", CVPR Workshops 2014

1. Train on Imagenet



2. Small Dataset (C classes)



3. Bigger dataset

	very similar dataset	**very different dataset**
very little data	Use Linear Classifier on top layer	You're in trouble… Try linear classifier from different stages
quite a lot of data	Finetune a few layers	Finetune a larger number of layers

Summary

- Feature Extraction vs. Fine-Tuning:
  - Feature extraction usually refers to freeze the bottom (early layers) and retrain the top (last) layer
  - Fine-Tuning usually refers to retrain the last few layers or the whole network ninialized from pretrained parameters
  - They are both called transfer learning
- Jupyter notebook examples with pytorch:
  - https://github.com/aifin-hkust/aifin-hkust.github.io/blob/master/2020/notebook/finetuning_resnet.ipynb

Prevalence of Neural Collapse during the terminal phase of deep learning training

Papyan, Han, and Donoho (2020), PNAS. arXiv:2008.08186

Neural Collapse phenomena, in post-zero-training-error phase

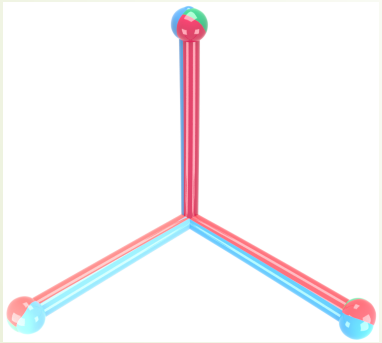
- **(NC1) Variability collapse:** As training progresses, the within-class variation of the activations becomes negligible as these activations collapse to their class-means.
- **(NC2) Convergence to Simplex ETF:** The vectors of the class-means (after centering by their global-mean) converge to having equal length, forming equal-sized angles between any given pair, and being the maximally pairwise-distanced configuration constrained to the previous two properties. This configuration is identical to a previously studied configuration in the mathematical sciences known as Simplex **Equiangular Tight Frame (ETF).**

- *Papyan, Han, and Donoho (2020), PNAS. arXiv:2008.0818**6***
- Visualization: https://purl.stanford.edu/br193mh4244

Definition 1 (**Simplex ETF**). A *standard* Simplex ETF is a collection of points in $\mathbb{R}^C$ specified by the columns of

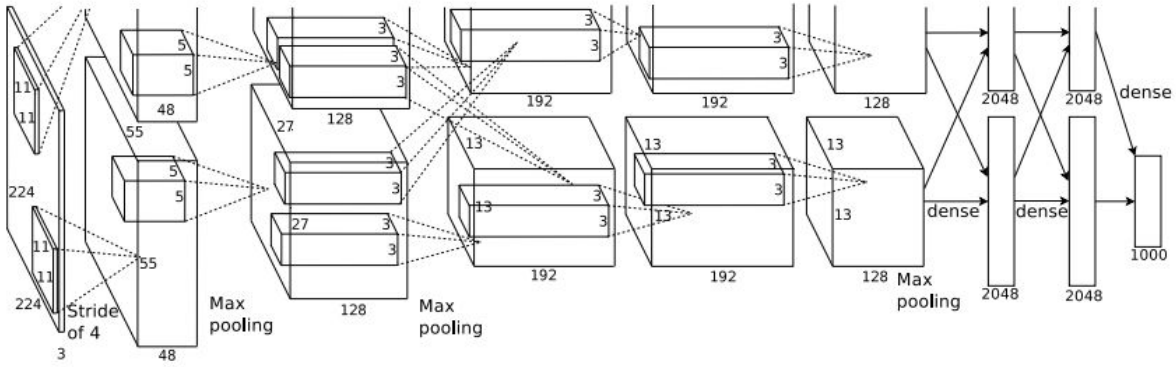
$$\boldsymbol{M}^\star = \sqrt{\frac{C}{C-1}}\left(\boldsymbol{I} - \frac{1}{C}\mathbb{1}\mathbb{1}^\top\right), \qquad [1]$$

where $\boldsymbol{I} \in \mathbb{R}^{C\times C}$ is the identity matrix, and $\mathbb{1}_C \in \mathbb{R}^C$ is the ones vector. In this paper, we allow other poses, as well as rescaling, so the *general* Simplex ETF consists of the points specified by the columns of $\boldsymbol{M} = \alpha \boldsymbol{U}\boldsymbol{M}^\star \in \mathbb{R}^{p\times C}$, where $\alpha \in \mathbb{R}_+$ is a scale factor, and $\boldsymbol{U} \in \mathbb{R}^{p\times C}$ $(p \geq C)$ is a partial orthogonal matrix $(\boldsymbol{U}^\top \boldsymbol{U} = \boldsymbol{I})$.



Visualizing Convolutional Networks

Understanding intermediate neurons?



Class Scores:
1000 numbers

Input Image:
3 x 224 x 224

What are the intermediate features looking for?

Visualizing CNN Features: Gradient Ascent

- **Gradient ascent**: Generate a synthetic image that maximally activates a neuron

$$I^* = \arg\max_I \boxed{f(I)} + \boxed{R(I)}$$

Neuron value

Natural image regularizer

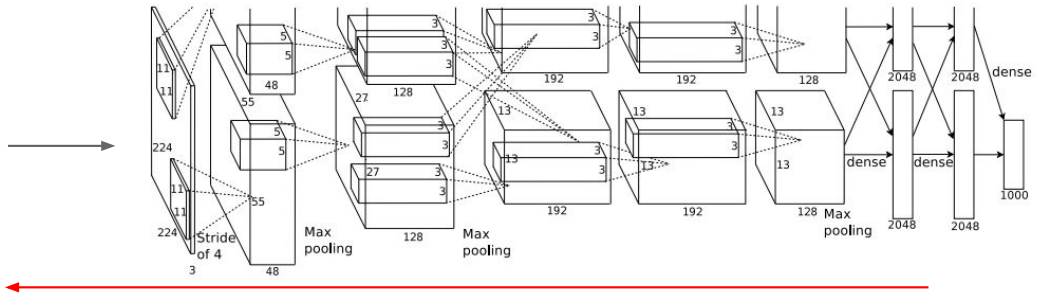
Visualizing CNN Features: Gradient Ascent

$$\arg\max_I S_c(I) - \lambda \|I\|_2^2$$

score for class c (before Softmax)

1. Initialize image to zeros

zero image



Repeat:

2. Forward image to compute current scores
3. Backprop to get gradient of neuron value with respect to image pixels
4. Make a small update to the image

Visualizing CNN Features: Gradient Ascent

$$\arg\max_I S_c(I) - \lambda \|I\|_2^2$$

Better regularizer: Penalize L2 norm of image; also during optimization periodically

(1) Gaussian blur image
(2) Clip pixels with small values to 0
(3) Clip pixels with small gradients to 0

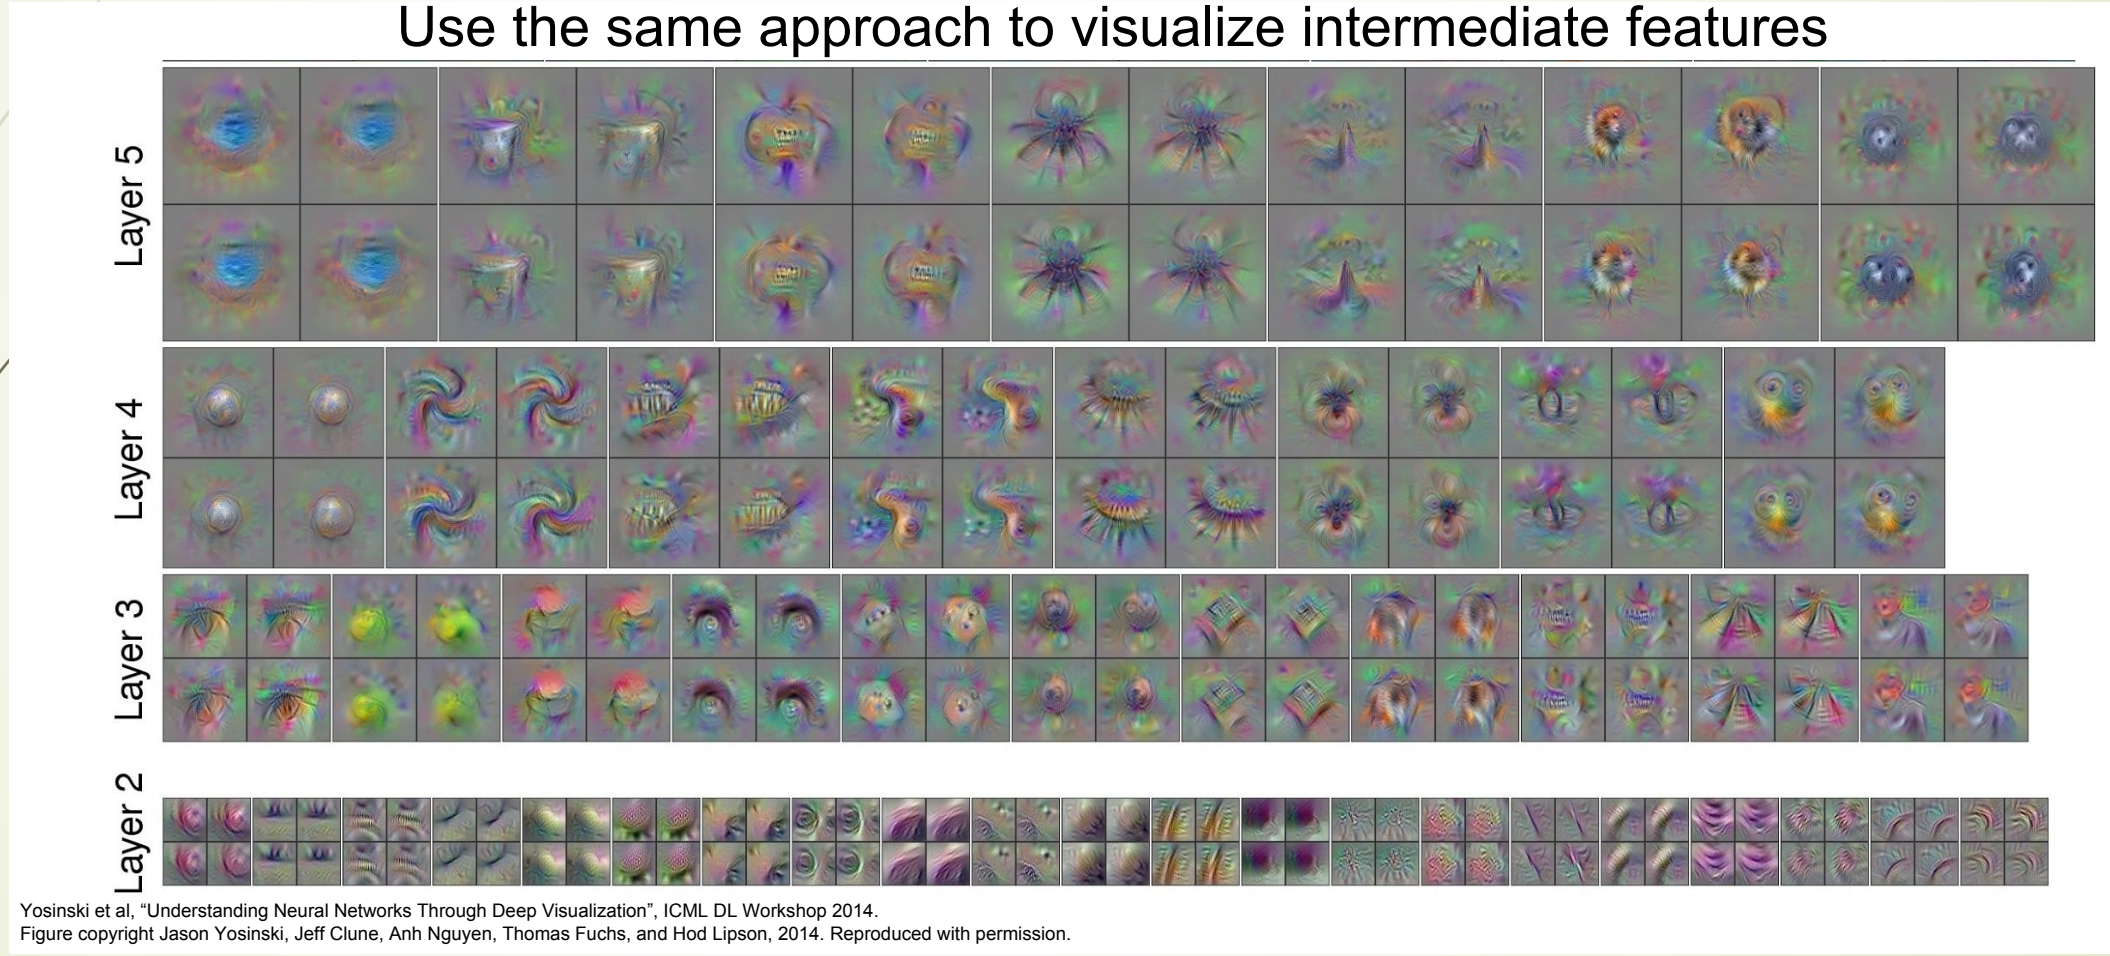
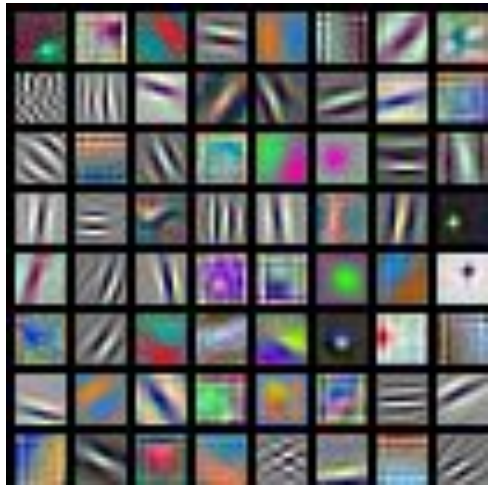
Visualizing CNN Features: Gradient Ascent



Yosinski et al, "Understanding Neural Networks Through Deep Visualization", ICML DL Workshop 2014.

It's easy to visualize early layers

First Layer: Visualize Filters

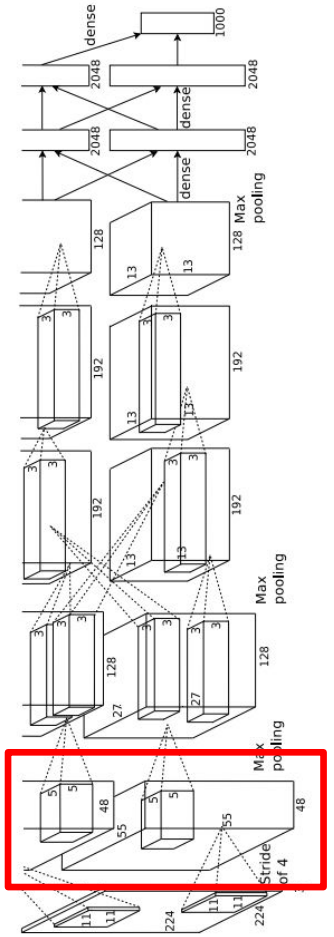


AlexNet:
64 x 3 x 11 x 11

ResNet-18:
64 x 3 x 7 x 7

ResNet-101:
64 x 3 x 7 x 7

DenseNet-121:
64 x 3 x 7 x 7



Krizhevsky, "One weird trick for parallelizing convolutional neural networks", arXiv 2014
He et al, "Deep Residual Learning for Image Recognition", CVPR 2016
Huang et al, "Densely Connected Convolutional Networks", CVPR 2017

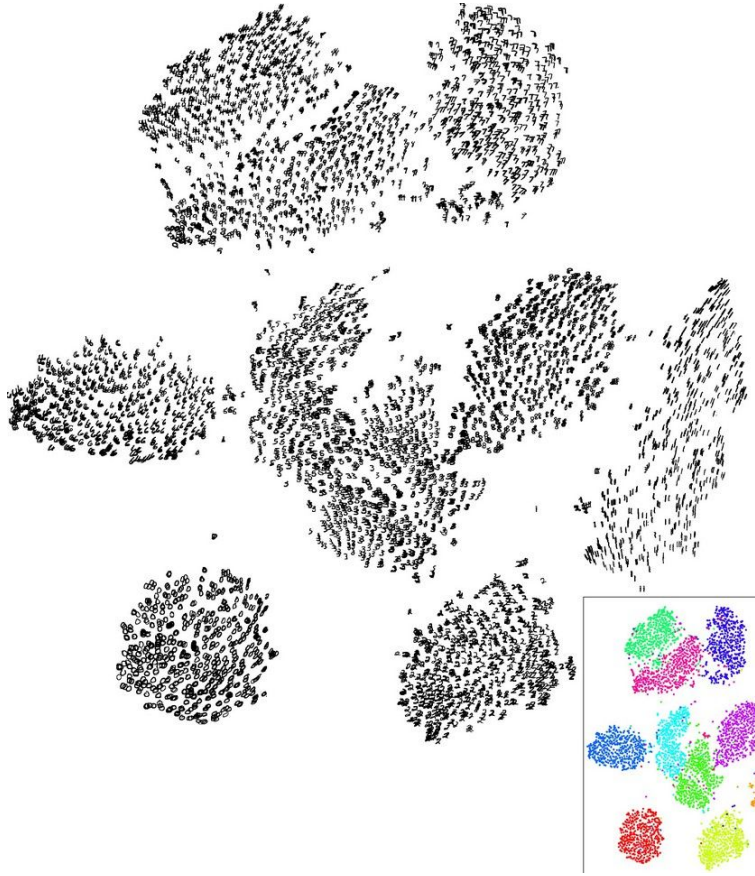
Last layers are hard to visualize

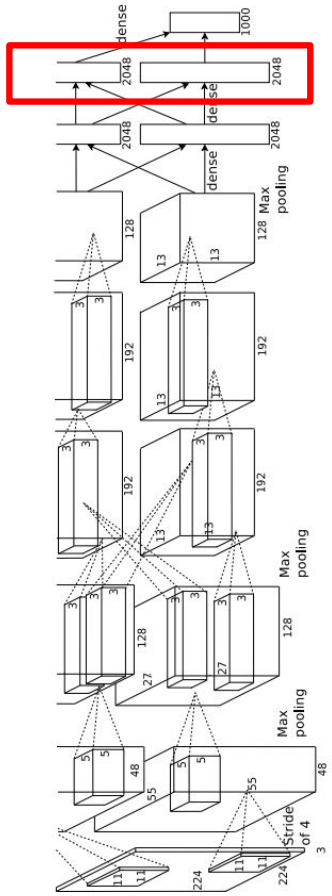
Last Layer: Dimensionality Reduction

Visualize the “space” of FC7 feature vectors by reducing dimensionality of vectors from 4096 to 2 dimensions

Simple algorithm: Principle Component Analysis (PCA)

More complex: **t-SNE**

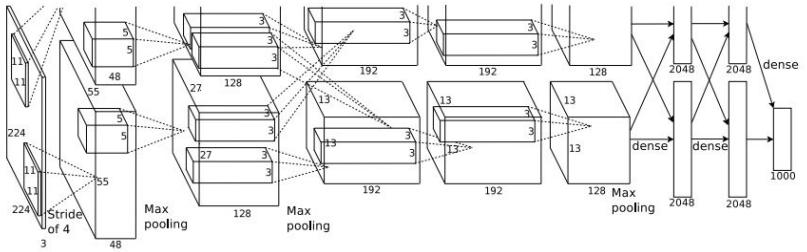




Van der Maaten and Hinton, “Visualizing Data using t-SNE”, JMLR 2008

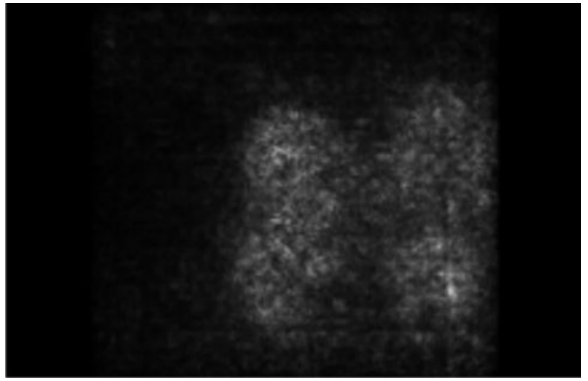
Saliency Maps

How to tell which pixels matter for classification?



Dog

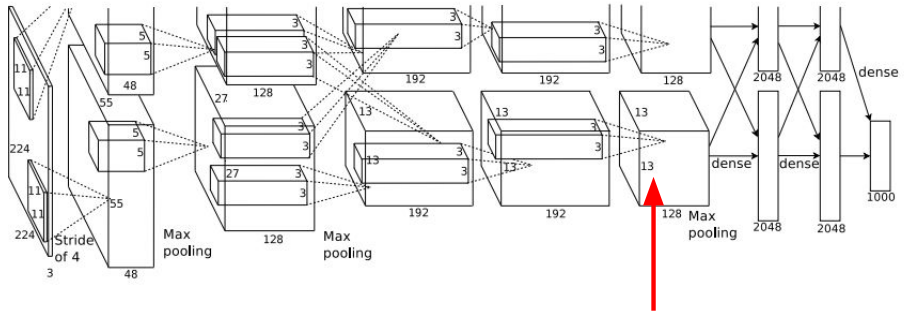
Compute gradient of (unnormalized) class score with respect to image pixels, take absolute value and max over RGB channels



Simonyan, Vedaldi, and Zisserman, “Deep Inside Convolutional Networks: Visualising Image Classification Models and Saliency Maps”, ICLR Workshop 2014.

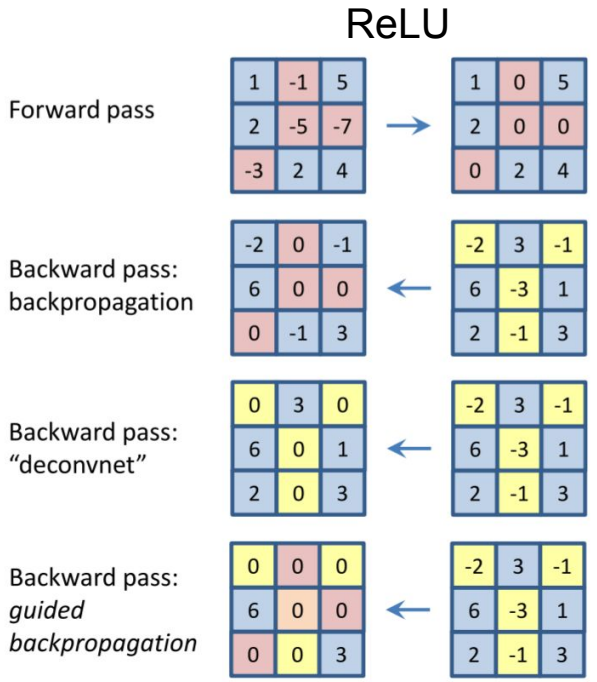
Guided BP

Intermediate features via (guided) backprop



Pick a single intermediate neuron, e.g. one value in 128 x 13 x 13 conv5 feature map

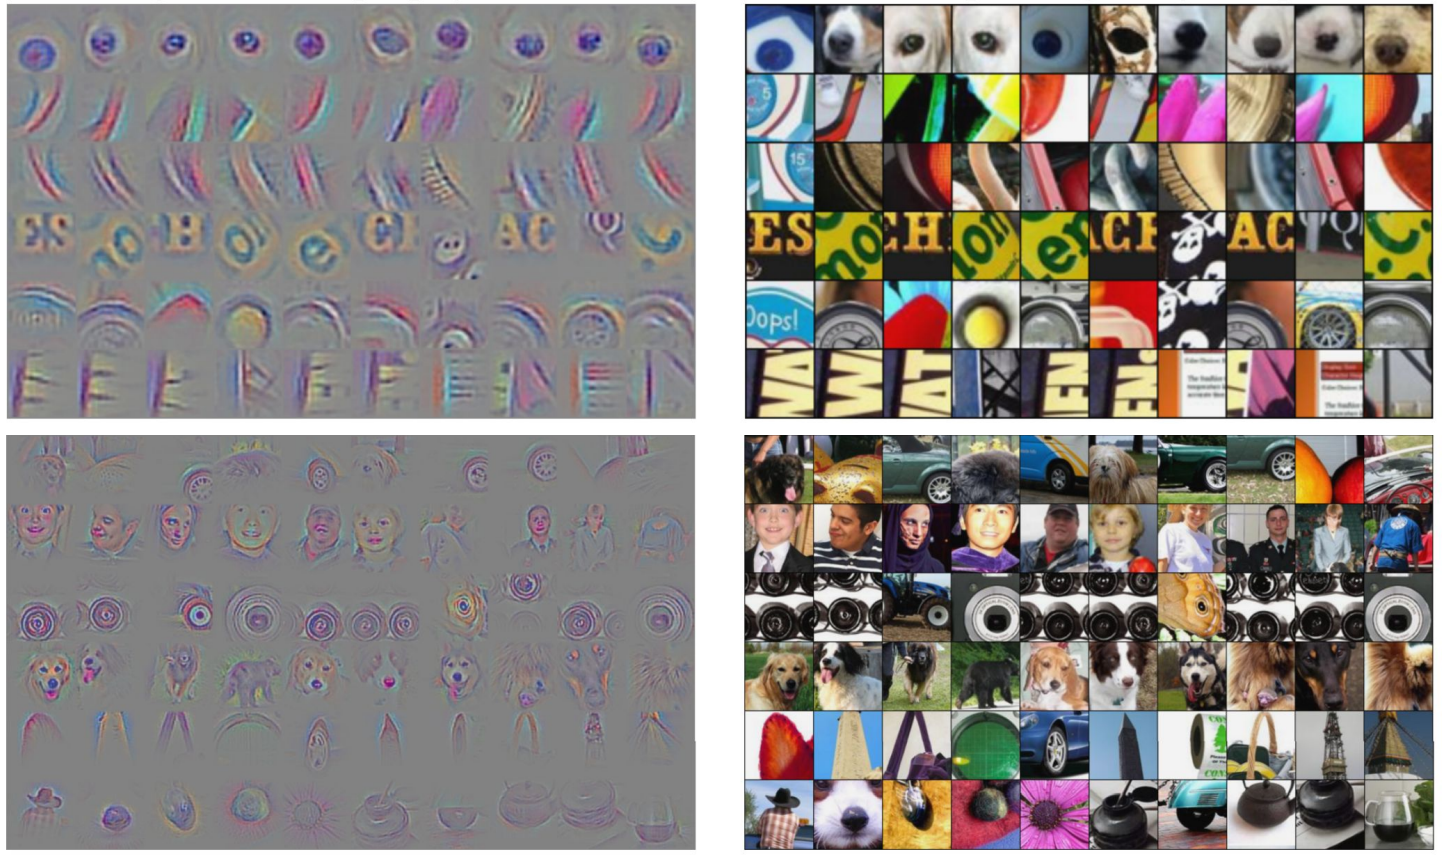
Compute gradient of neuron value with respect to image pixels



Images come out nicer if you only backprop positive gradients through each ReLU (guided backprop)

Zeiler and Fergus, "Visualizing and Understanding Convolutional Networks", ECCV 2014
Springenberg et al, "Striving for Simplicity: The All Convolutional Net", ICLR Workshop 2015

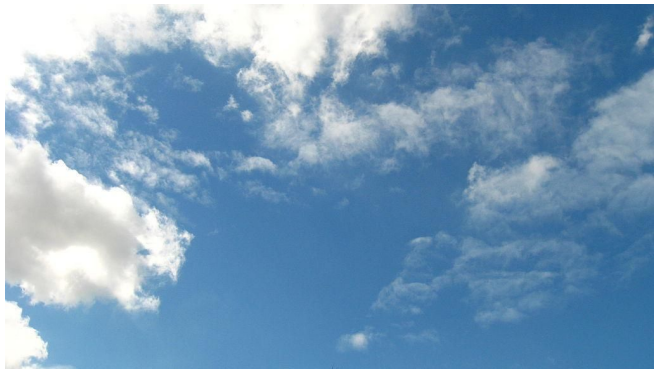
Intermediate features via Guided BP

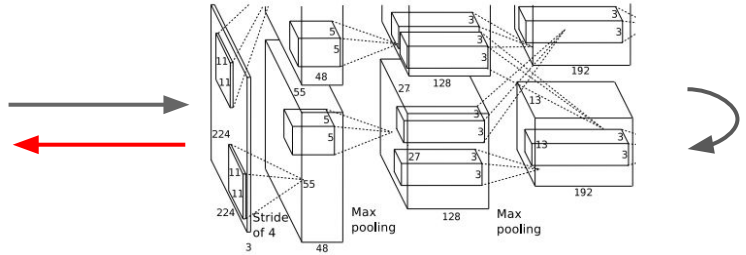


Zeiler and Fergus, “Visualizing and Understanding Convolutional Networks”, ECCV 2014
Springenberg et al, “Striving for Simplicity: The All Convolutional Net”, ICLR Workshop 2015

DeepDream: amplifying features

Rather than synthesizing an image to maximize a specific neuron, instead try to **amplify** the neuron activations at some layer in the network





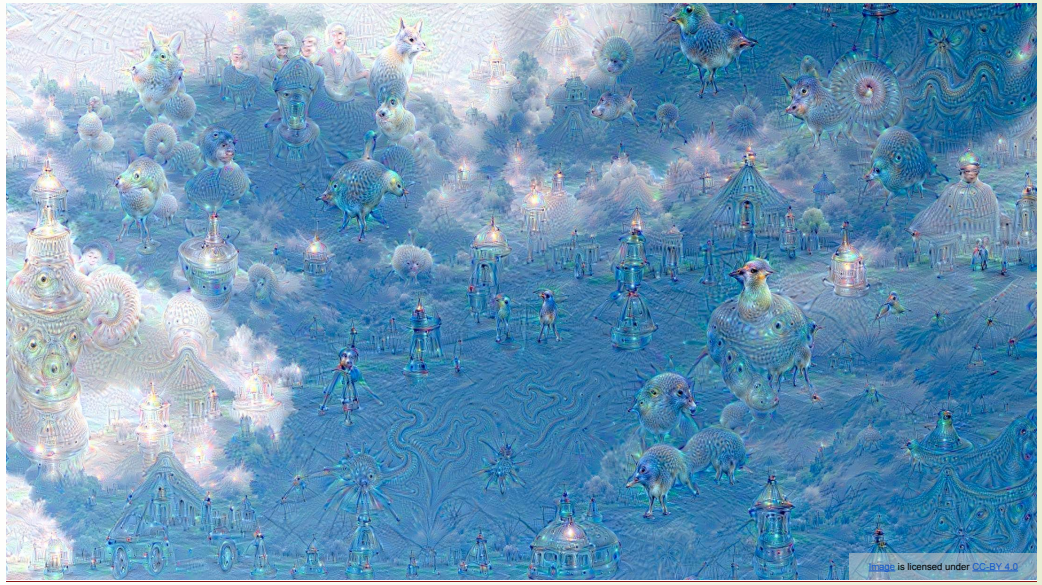
Choose an image and a layer in a CNN; repeat:

1. Forward: compute activations at chosen layer
2. Set gradient of chosen layer *equal to its activation*
3. Backward: Compute gradient on image
4. Update image

Equivalent to:

$$I^* = \arg\max_I \sum_i f_i(I)^2$$

Example: DeepDream of Sky



"Admiral Dog!"

"The Pig-Snail"

"The Camel-Bird"

"The Dog-Fish"

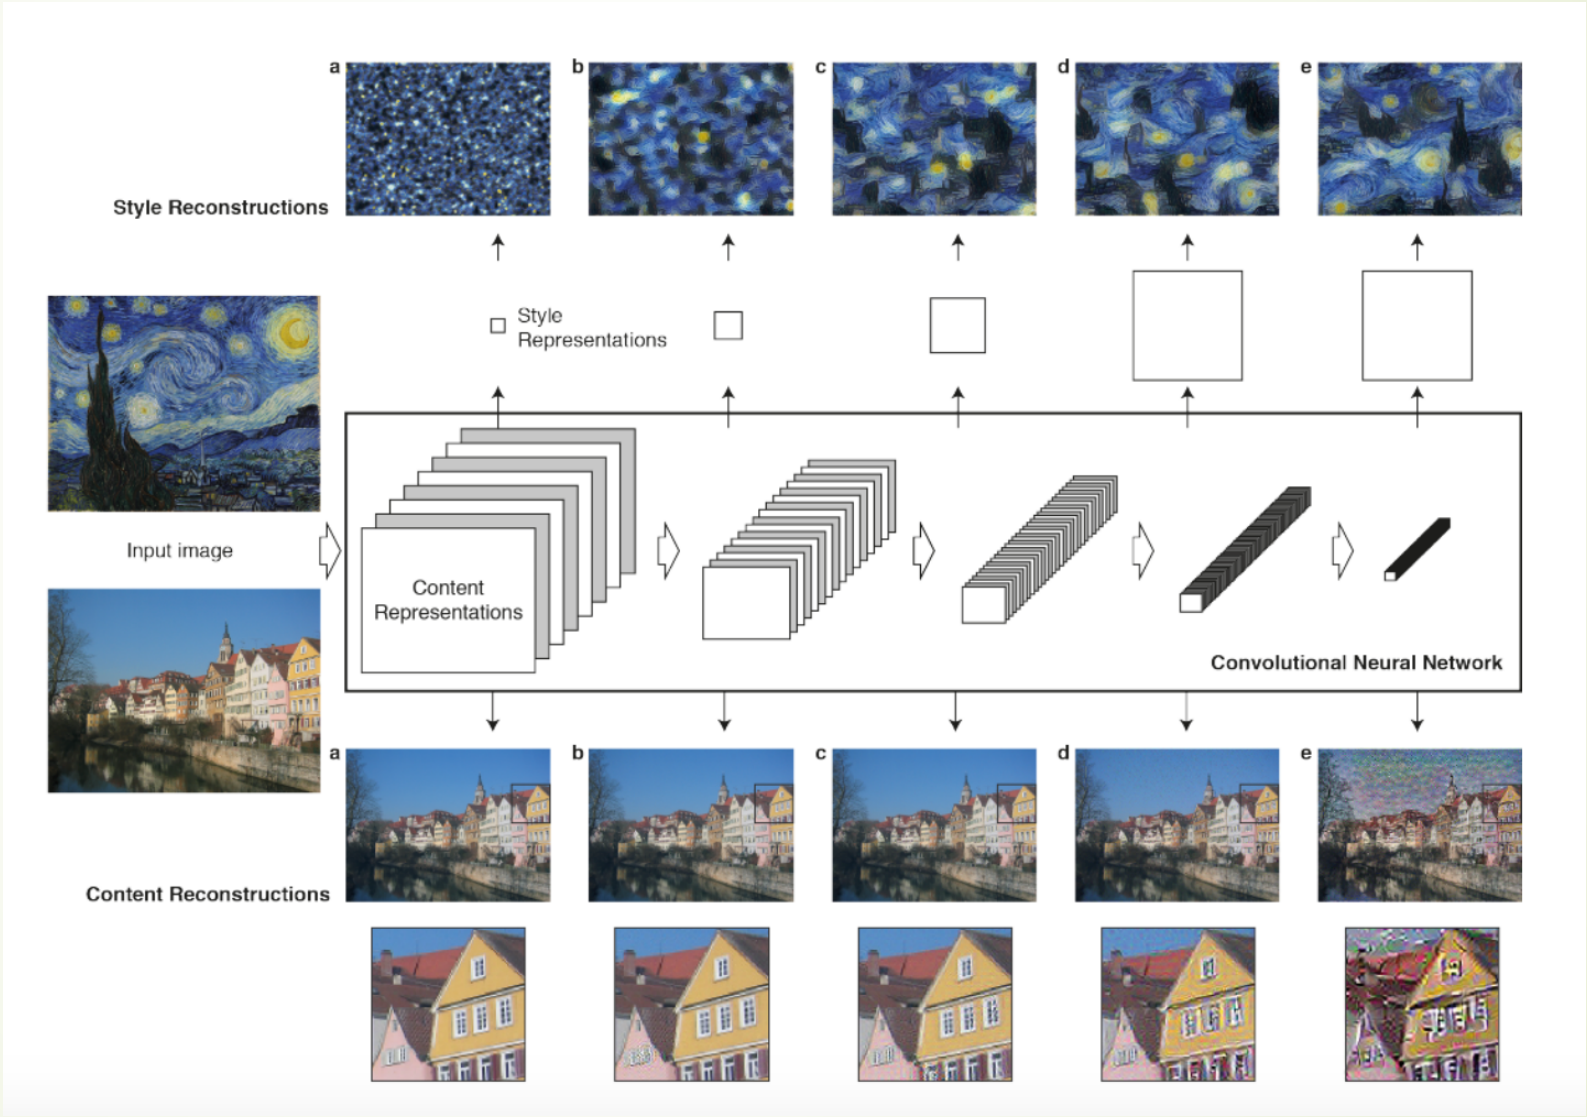
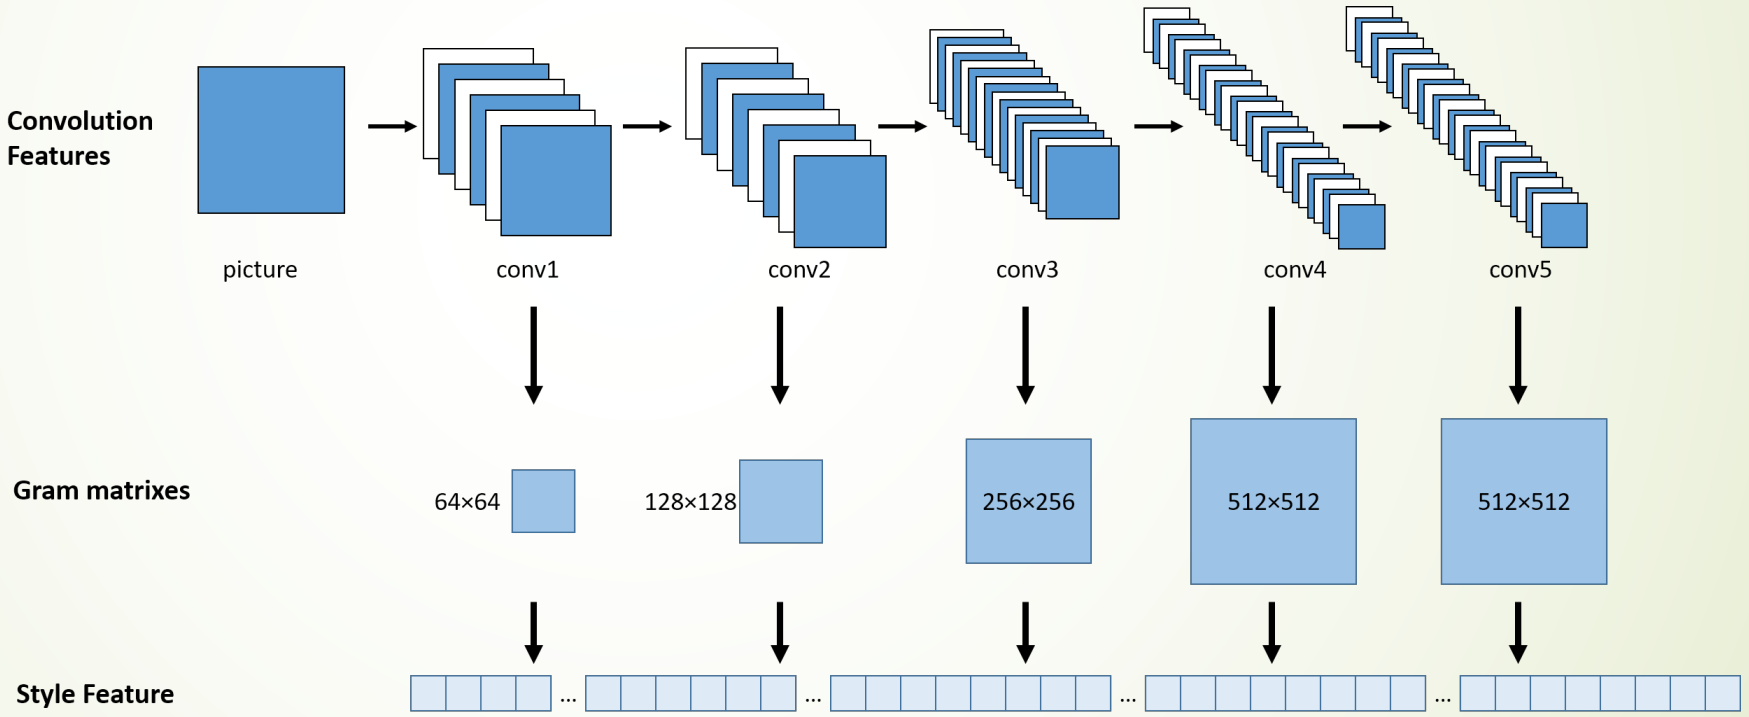
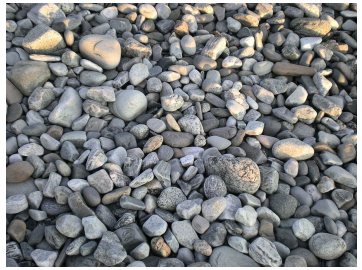
Style-Content Feature Extraction



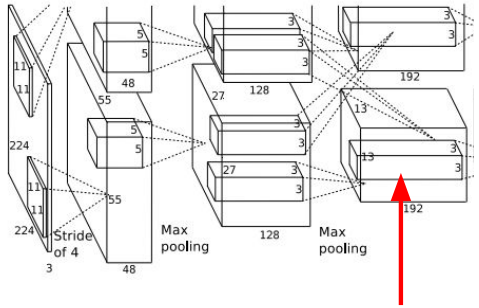
Style Features as Second Order Statistics

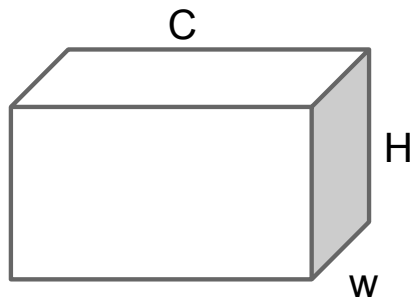


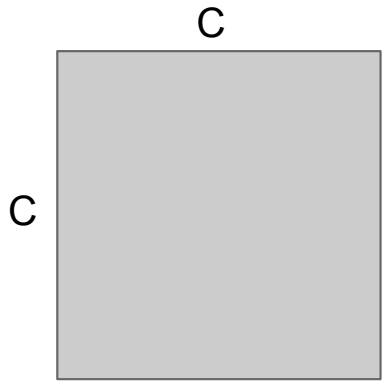
Gram Matrix as Style Features



This image is in the public domain.







Each layer of CNN gives C x H x W tensor of features; H x W grid of C-dimensional vectors

Outer product of two C-dimensional vectors gives C x C matrix measuring co-occurrence

Average over all HW pairs of vectors, giving **Gram matrix** of shape C x C

Efficient to compute; reshape features from

C x H x W to =C x HW

then compute $G = FF^T$

Neural Texture Synthesis

$$E_l = \frac{1}{4N_l^2 M_l^2} \sum_{i,j} \left(G_{ij}^l - \hat{G}_{ij}^l\right)^2 \qquad \mathcal{L}(\vec{x}, \hat{\vec{x}}) = \sum_{l=0}^{L} w_l E_l$$

1. Pretrain a CNN on ImageNet (VGG-19)
2. Run input texture forward through CNN, record activations on every layer; layer i gives feature map of shape $C_i \times H_i \times W_i$
3. At each layer compute the *Gram matrix* giving outer product of features:

$$G_{ij}^l = \sum_k F_{ik}^l F_{jk}^l \text{ (shape } C_i \times C_i\text{)}$$

4. Initialize generated image from random noise
5. Pass generated image through CNN, compute Gram matrix on each layer
6. Compute loss: weighted sum of L2 distance between Gram matrices
7. Backprop to get gradient on image
8. Make gradient step on image
9. GOTO 5

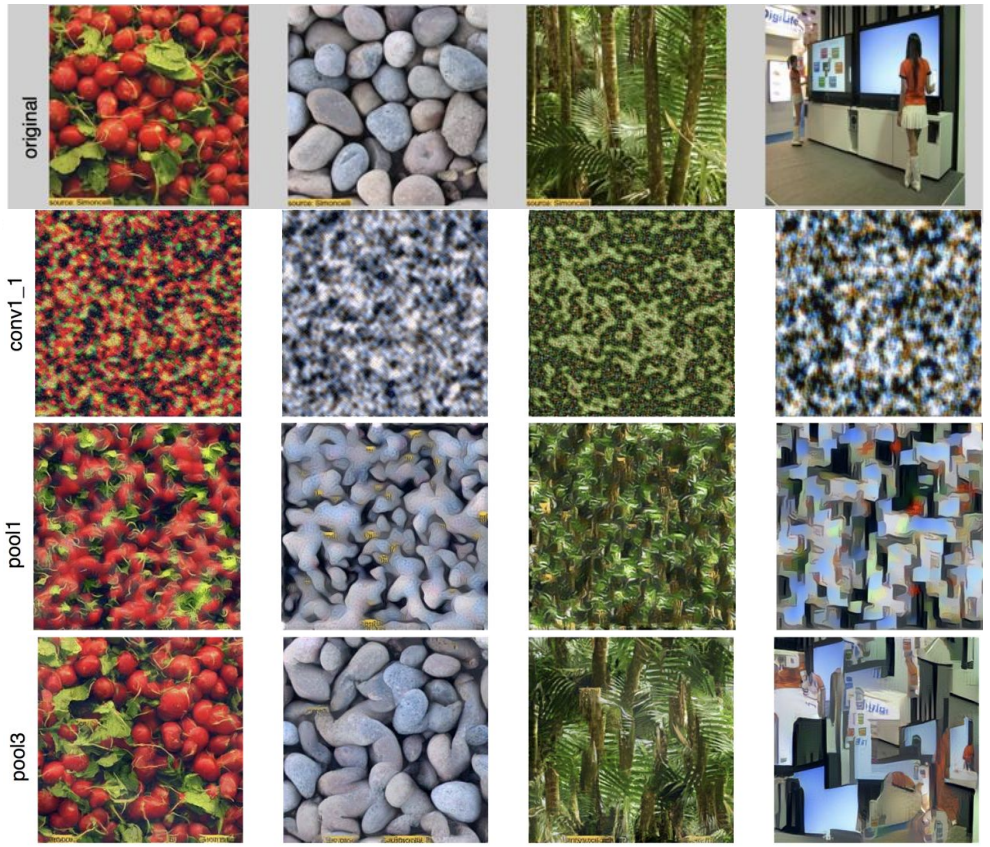
Neural Texture Synthesis

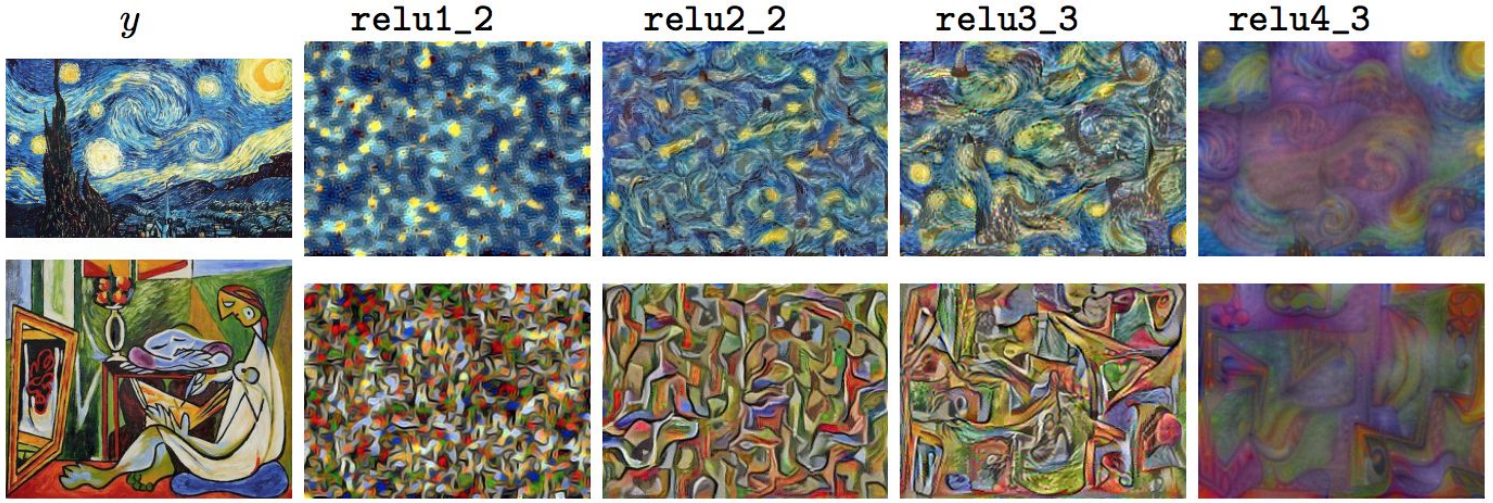
Reconstructing texture from higher layers recovers larger features from the input texture



Gatys, Ecker, and Bethge, “Texture Synthesis Using Convolutional Neural Networks”, NIPS 2015

Neural Texture Synthesis: Gram Reconstruction

Texture synthesis (Gram reconstruction)



Feature Inversion

Given a CNN feature vector for an image, find a new image that:

- Matches the given feature vector
- "looks natural" (image prior regularization)

$$\mathbf{x}^* = \underset{\mathbf{x} \in \mathbb{R}^{H \times W \times C}}{\operatorname{argmin}} \ \ell(\Phi(\mathbf{x}), \Phi_0) + \lambda \mathcal{R}(\mathbf{x})$$

Given feature vector

Features of new image

$$\ell(\Phi(\mathbf{x}), \Phi_0) = \|\Phi(\mathbf{x}) - \Phi_0\|^2$$

$$\mathcal{R}_{V^\beta}(\mathbf{x}) = \sum_{i,j} \left((x_{i,j+1} - x_{ij})^2 + (x_{i+1,j} - x_{ij})^2 \right)^{\frac{\beta}{2}}$$

Total Variation regularizer
(encourages spatial smoothness)

Combined Loss for both Content (1st order statistics) and Style (2nd order statistics: Gram)

$$\mathcal{L}_{content}(\vec{p}, \vec{x}, l) = \frac{1}{2} \sum_{i,j} \left(F_{ij}^{l} - P_{ij}^{l} \right)^2 \ .$$

$$\mathcal{L}_{style}(\vec{a}, \vec{x}) = \sum_{l=0}^{L} w_l E_l$$

where

$$E_l = \frac{1}{4N_l^2 M_l^2} \sum_{i,j} \left(G_{ij}^{l} - A_{ij}^{l} \right)^2 \qquad G_{ij}^{l} = \sum_{k} F_{ik}^{l} F_{jk}^{l}.$$

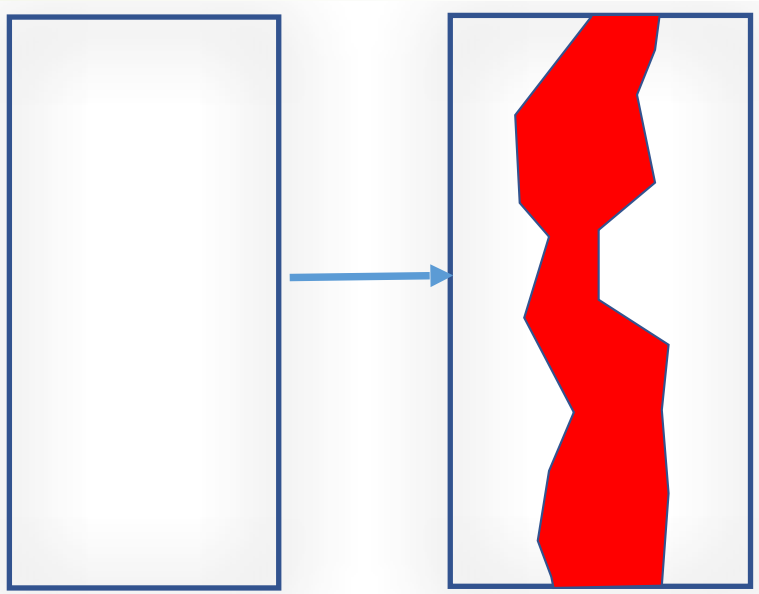
Lottery Ticket Hypothesis for Efficient Subnets in Deep Learning



Over-parameterized Networks W

Compressive Networks W_s

Lottery Ticket Hypothesis

- *Dense, randomly-initialized, feed-forward networks contain subnetworks (winning tickets) that – when trained in isolation – reach test accuracy comparable to the original network in a similar number of iterations.* (Frankle & Carbin, 2019)

Rewinding the network from the initialization, and find "winning ticket" subnet

Split LBI finds efficient sparse architecture

Texture bias in ImageNet training

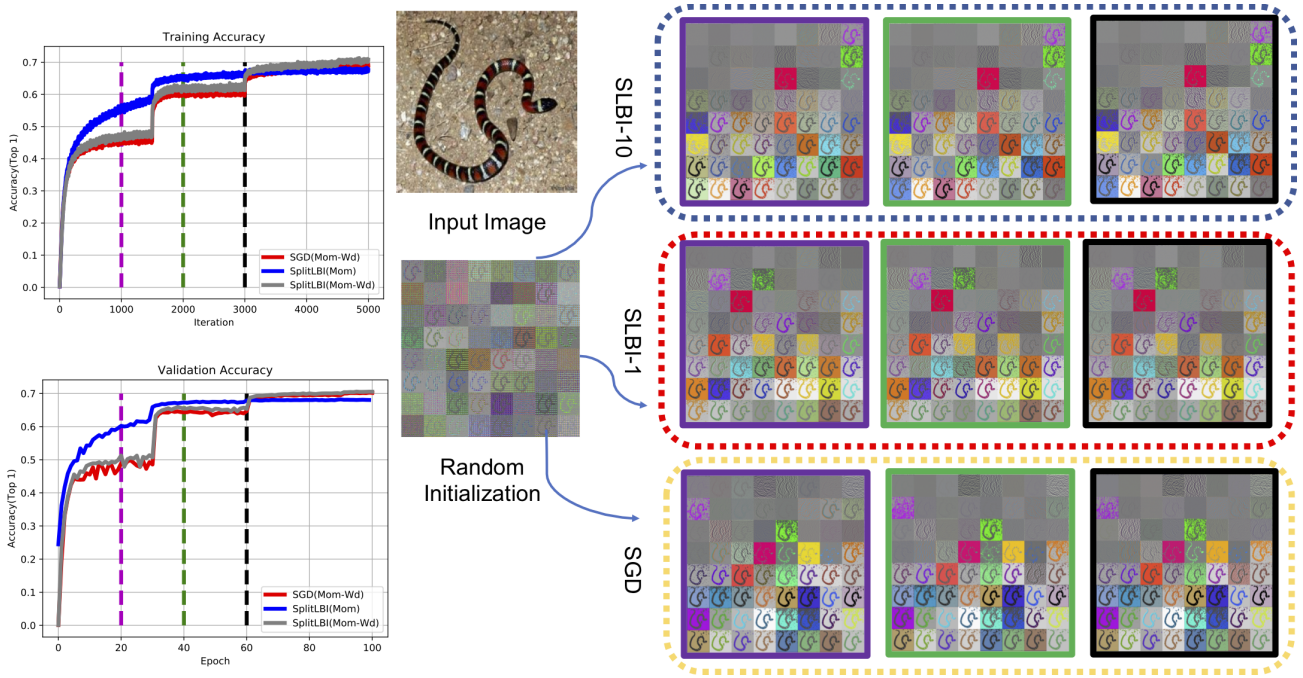

Figure: Visualization of the first convolutional layer filters of ResNet-18 trained on ImageNet-2012, where texture features are more important than colour/shapes. Given the input image and initial weights visualized in the middle, filter response gradients at 20 (purple), 40 (green), and 60 (black) epochs are visualized. SGD with Momentum (Mom) and Weight Decay (WD), is compared with SLBI.

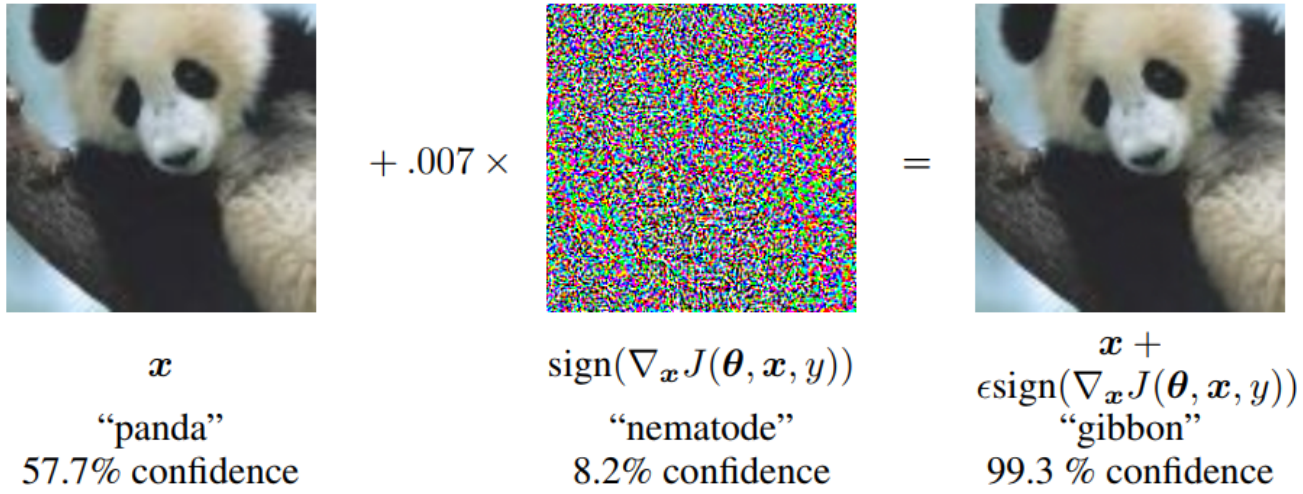
Adversarial Examples and Robustness

Deep Learning may be fragile: adversarial examples



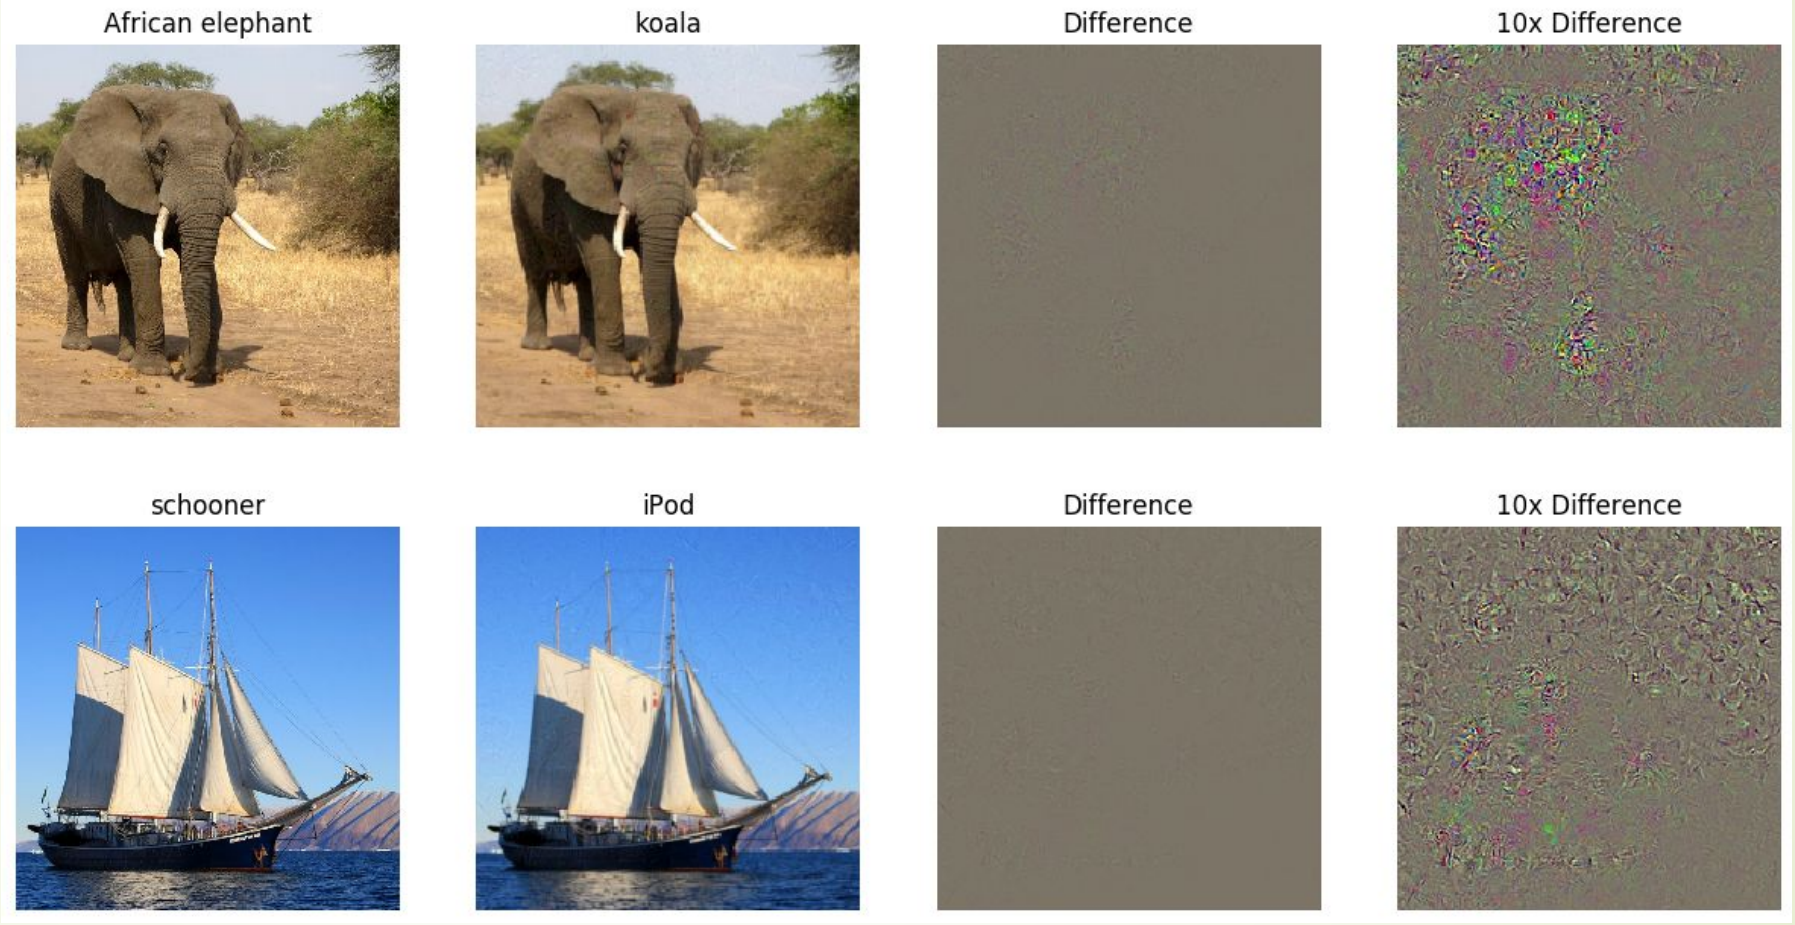
[Goodfellow et al., 2014]

- Small but malicious perturbations can result in severe misclassification
- Malicious examples generalize across different architectures
- What is source of instability?
- Can we robustify network?

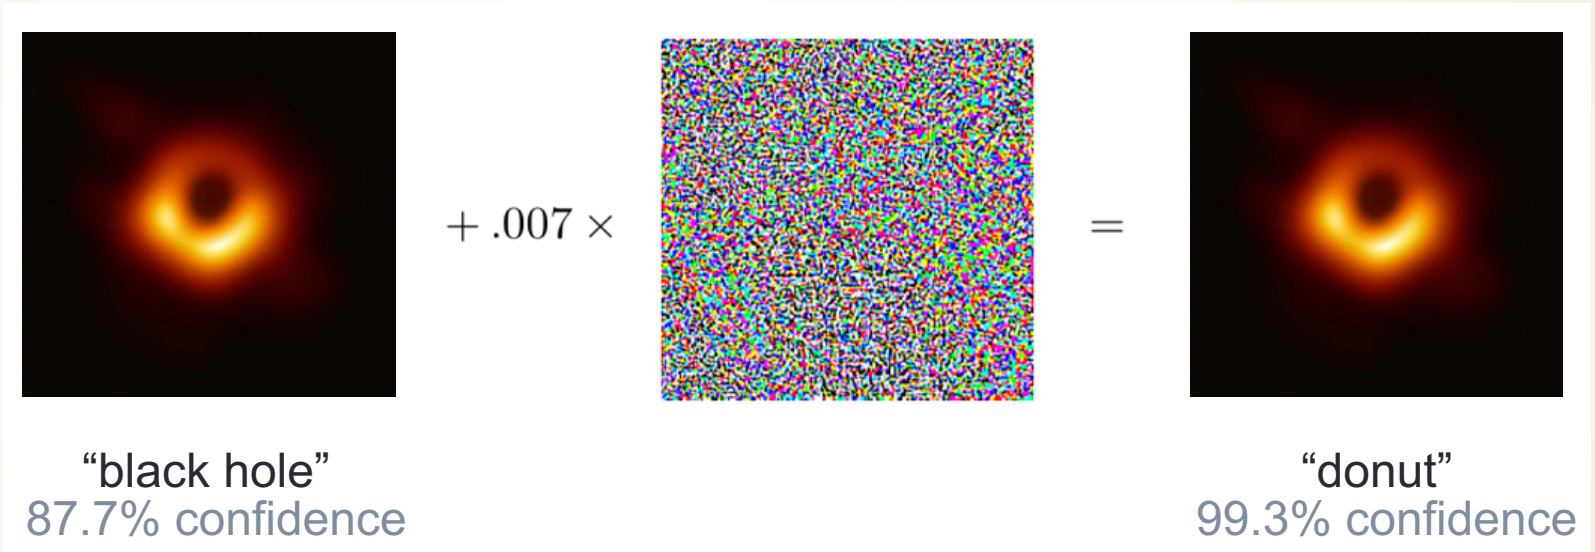
Adversarial Examples: Fooling Images

- Start from an arbitrary image
- Pick an arbitrary class
- Modify the image to maximize the class
- Repeat until network is fooled

Fooling Images/Adversarial Examples

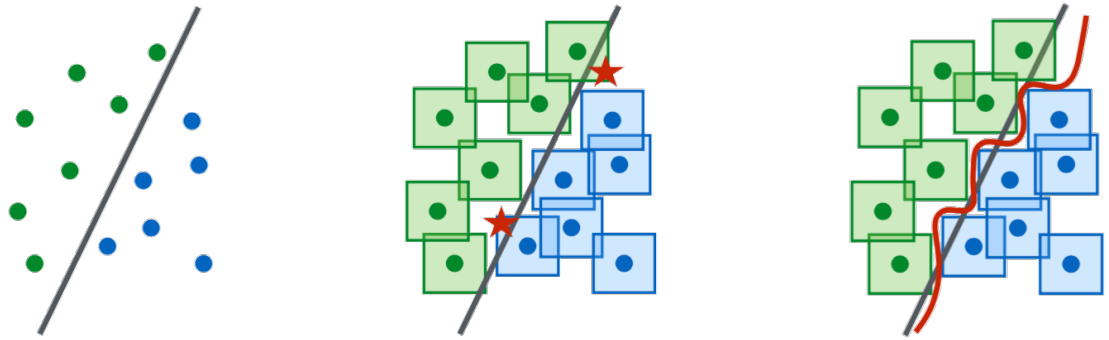


Convolutional Networks lack Robustness



Courtesy of Dr. Hongyang ZHANG.

Adversarial Robust Training



- Traditional training:

$$\min_{\theta} J_n(\theta, \mathbf{z} = (x_i, y_i)_{i=1}^n)$$

  - e.g. square or cross-entropy loss as negative log-likelihood of logit models

- Robust optimization (Madry et al. ICLR'2018):

$$\min_{\theta} \max_{\|\epsilon_i\| \leq \delta} J_n(\theta, \mathbf{z} = (x_i + \epsilon_i, y_i)_{i=1}^n)$$

  - robust to any distributions, yet computationally hard
