# An Introduction to Convolutional Neural Networks

Yuan YAO  
HKUST

# Summary

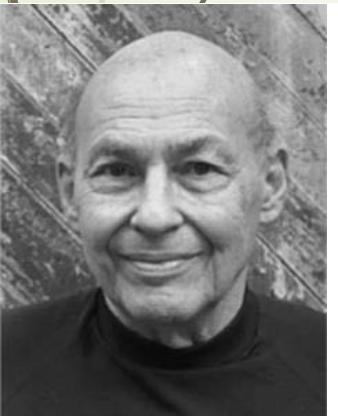

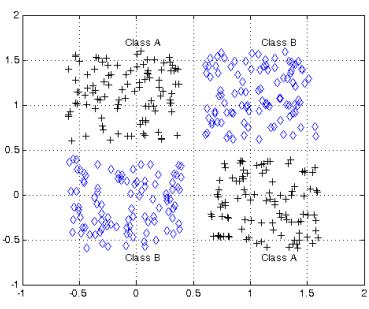

- ▶ We had covered so far
  - ▶ Linear models (linear and logistic regression) – always a good start, simple yet powerful
  - ▶ Model Assessment and Selection – basics for all methods
  - ▶ Trees, Random Forests, and Boosting – good for high dim mixed-type heterogeneous features
  - ▶ Support Vector Machines – good for small amount of data but high dim geometric features
- ▶ Next, neural networks for unstructured data (image, language etc.):
  - ▶ **Convolutional Neural Networks** – image data
  - ▶ Recurrent Neural Networks, LSTM – sequence data
  - ▶ Transformer, BERT – machine translation etc.
  - ▶ Generative models and GANs – new unsupervised learning for image, etc.
  - ▶ Reinforcement Learning – Markov decision process, playing games, etc.

# Locality or Sparsity of Computation

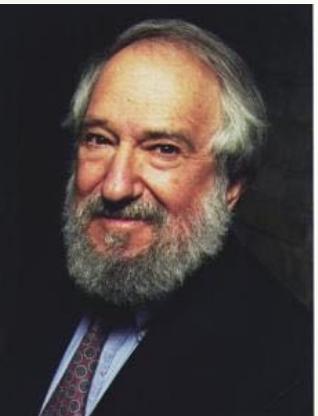

Minsky and Papert, 1969

Perceptron can't do **XOR** classification

Perceptron needs infinite global  
information to compute **connectivity**

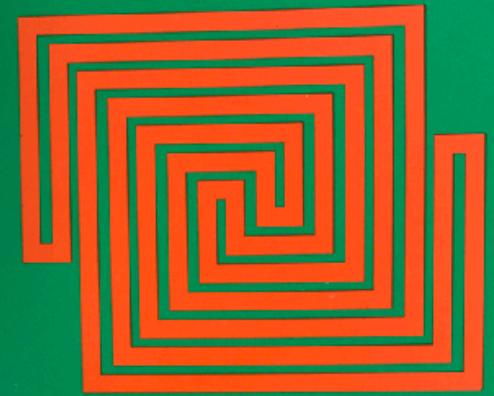

Marvin Minsky

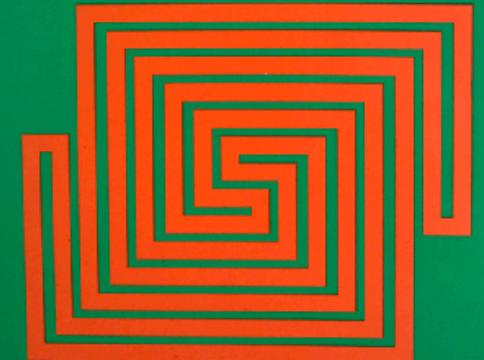

Seymour Papert

**Locality** or **Sparsity** is important:  
Locality in time?  
Locality in space?

Expanded Edition

Perceptrons

Marvin L. Minsky  
Seymour A. Papert

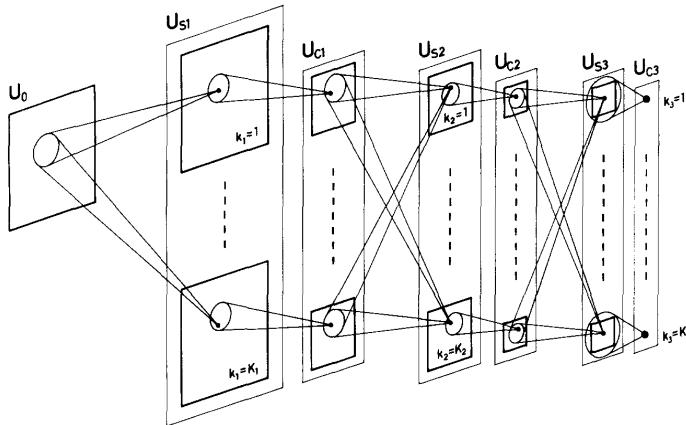

# Convolutional Neural Networks: shift invariances and locality for images

Biol. Cybernetics 36, 193–202 (1980)

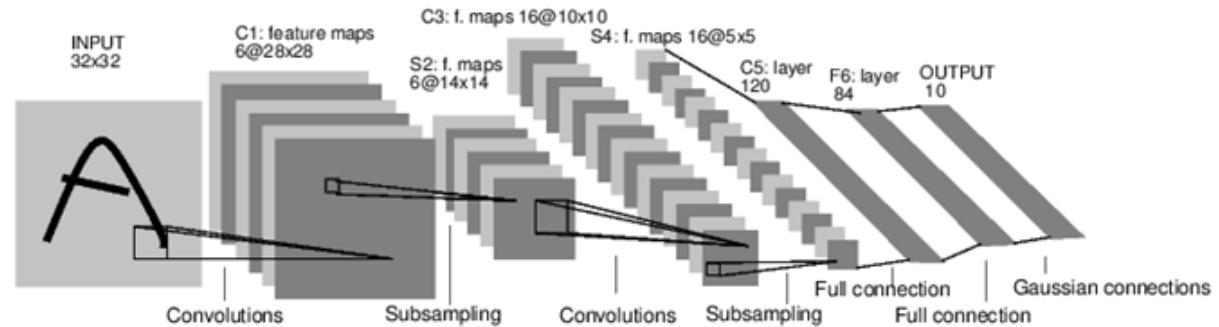

**Neocognitron: A Self-organizing Neural Network Model for a Mechanism of Pattern Recognition Unaffected by Shift in Position**

Kunihiko Fukushima

NHK Broadcasting Science Research Laboratories, Kinuta, Setagaya, Tokyo, Japan

- Can be traced to *Neocognitron* of Kunihiko Fukushima (1979)
- Yann LeCun combined convolutional neural networks with back propagation (1989)
- Imposes **shift invariance** and **locality** on the weights
- Forward pass remains similar
- Backpropagation slightly changes – need to sum over the gradients from all spatial positions

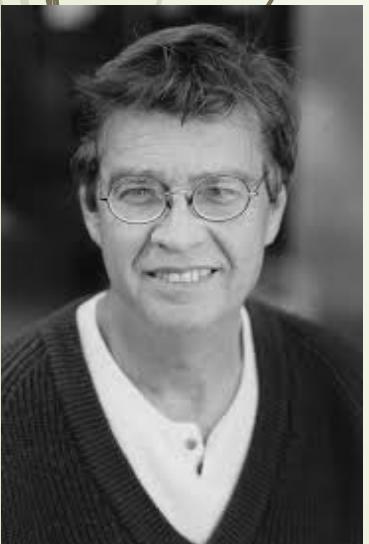

# Multilayer Perceptrons (MLP) and Back-Propagation (BP) Algorithms

Rumelhart, Hinton, Williams (1986)

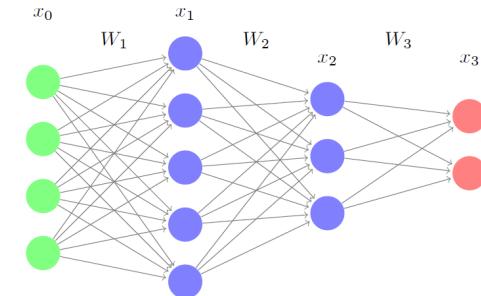

Learning representations by back-propagating errors, Nature, 323(9): 533-536

BP algorithms as **stochastic gradient descent** algorithms (**Robbins–Monro 1950; Kiefer–Wolfowitz 1951**) with Chain rules of Gradient maps

MLP classifies **XOR**, but the global hurdle on topology (connectivity) computation still exists

NATURE VOL. 323 9 OCTOBER 1986 LETTERS TO NATURE 533

## Learning representations by back-propagating errors

David E. Rumelhart\*, Geoffrey E. Hinton†  
& Ronald J. Williams\*

\* Institute for Cognitive Science, C-015, University of California,  
San Diego, La Jolla, California 92093, USA  
† Department of Computer Science, Carnegie-Mellon University,  
Pittsburgh, Pennsylvania 15213, USA

more difficult when we introduce hidden units whose actual or desired states are not specified by the task. (In perceptrons, there are 'feature analysers' between the input and output that are not true hidden units because their input connections are fixed by hand, so their states are completely determined by the input vector: they do not learn representations.) The learning units should be active in order to help achieve the desired input-output behaviour. This amounts to deciding what these units should represent. We demonstrate that a general purpose and relatively simple procedure is powerful enough to construct appropriate learned representations.

The simplest form of the learning procedure is for layered networks which have a layer of input units at the bottom, any number of intermediate layers, and a layer of output units at the top. Connections within a layer or from higher to lower layers are forbidden, but connections can skip intermediate layers. An input vector is presented to the network by setting the states of the input units. Then the states of the units in each layer are determined by applying equations (1) and (2) to the connections coming from lower layers. All units within a layer have their states set in parallel, but different layers have their states set sequentially, starting at the bottom and working upwards until the states of the output units are determined.

There have been many attempts to design self-organizing neural networks. The aim is to find a powerful synaptic modification rule that will allow an arbitrarily connected neural network to develop an internal structure that is appropriate for a particular task domain. The task is specified by giving the desired state vector of the output units for each state vector of the input units. If the input units are directly connected to the output units it is relatively easy to find learning rules that iteratively adjust the relative strengths of the connections so as to progressively reduce the difference between the actual and desired output vectors\*. Learning becomes more interesting but

\* To whom correspondence should be addressed

$$x_j = \sum_i x_i w_{ij}$$

Units can be given biases by introducing an extra input to each unit which always has a value of 1. The weight on this extra input is called the bias and is equivalent to a threshold of the opposite sign. It can be treated just like the other weights.

A unit has a real-valued output,  $y_j$ , which is a non-linear function of its total input

$$y_j = \frac{1}{1 + e^{-x_j}}$$

# BP Algorithm: Forward Pass

- Cascade of repeated [linear operation followed by coordinatewise nonlinearity]'s
- Nonlinearities: sigmoid, hyperbolic tangent, (recently) ReLU.

---

## Algorithm 1 Forward pass

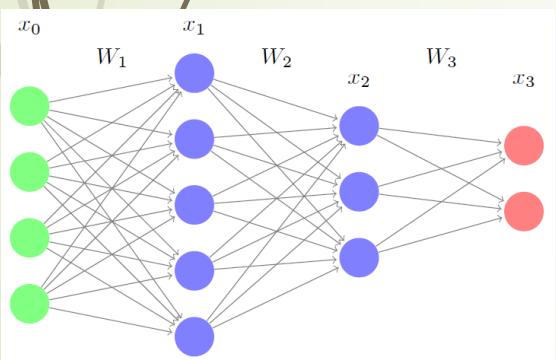

---

**Input:**  $x_0$

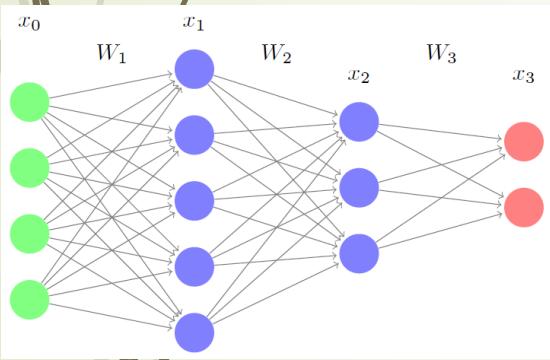

**Output:**  $x_L$

```
1: for  $\ell = 1$  to  $L$  do
2:    $x_\ell = f_\ell(W_\ell x_{\ell-1} + b_\ell)$ 
3: end for
```

---

# BP algorithm = Gradient Descent Method

- Training examples  $\{x_0^i\}_{i=1}^n$  and labels  $\{y^i\}_{i=1}^n$
- Output of the network  $\{x_L^i\}_{i=1}^m$
- Objective

$$J(\{W_l\}, \{b_l\}) = \frac{1}{n} \sum_{i=1}^n \frac{1}{2} \|y^i - x_L^i\|_2^2 \quad (1)$$

Other losses include cross-entropy, logistic loss, exponential loss, etc.

- Gradient descent

$$W_l = W_l - \eta \frac{\partial J}{\partial W_l}$$

$$b_l = b_l - \eta \frac{\partial J}{\partial b_l}$$

In practice: use Stochastic Gradient Descent (SGD)

# Derivation of BP: Lagrangian Multiplier

LeCun et al. 1988

Given  $n$  training examples  $(I_i, y_i) \equiv (\text{input}, \text{target})$  and  $L$  layers

- Constrained optimization

$$\min_{W,x} \quad \sum_{i=1}^n \|x_i(L) - y_i\|_2$$

$$\text{subject to} \quad x_i(\ell) = f_\ell \left[ W_\ell x_i(\ell-1) \right], \\ i = 1, \dots, n, \quad \ell = 1, \dots, L, \quad x_i(0) = I_i$$

- Lagrangian formulation (Unconstrained)

$$\min_{W,x,B} \mathcal{L}(W, x, B)$$

$$\mathcal{L}(W, x, B) = \sum_{i=1}^n \left\{ \|x_i(L) - y_i\|_2^2 + \sum_{\ell=1}^L B_i(\ell)^T \left( x_i(\ell) - f_\ell \left[ W_\ell x_i(\ell-1) \right] \right) \right\}$$

# back-propagation – derivation

- $\frac{\partial \mathcal{L}}{\partial B}$

## Forward pass

$$x_i(\ell) = f_\ell \left[ \underbrace{W_\ell x_i(\ell-1)}_{A_i(\ell)} \right] \quad \ell = 1, \dots, L, \quad i = 1, \dots, n$$

- $\frac{\partial \mathcal{L}}{\partial x}, z_\ell = [\nabla f_\ell] B(\ell)$

## Backward (adjoint) pass

$$z(L) = 2\nabla f_L \left[ A_i(L) \right] (y_i - x_i(L))$$

$$z_i(\ell) = \nabla f_\ell \left[ A_i(\ell) \right] W_{\ell+1}^T z_i(\ell+1) \quad \ell = 0, \dots, L-1$$

- $W \leftarrow W + \lambda \frac{\partial \mathcal{L}}{\partial W}$

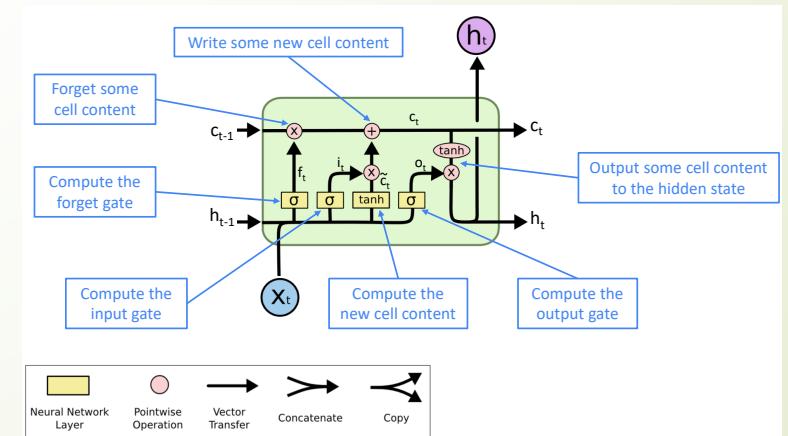

## Weight update

$$W_\ell \leftarrow W_\ell + \lambda \sum_{i=1}^n z_i(\ell) x_i^T(\ell-1)$$

# Long-Short-Term-Memory (LSTM, 1997)

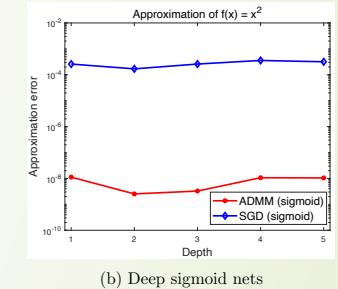

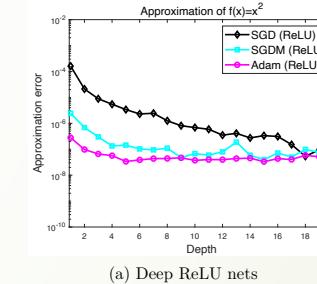

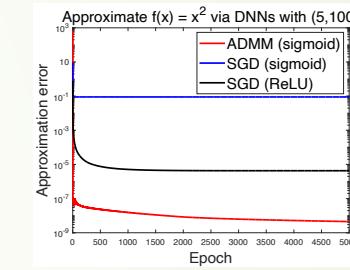

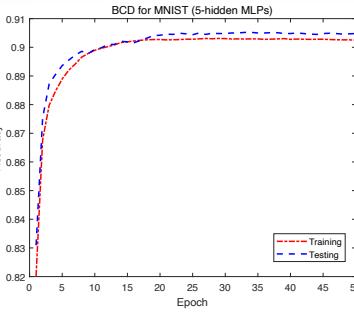

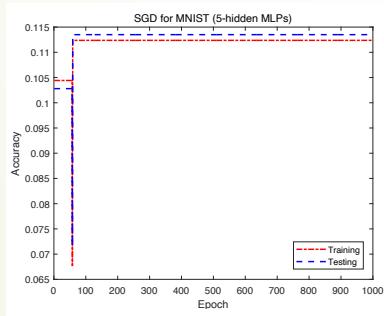

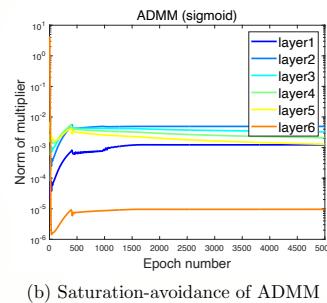

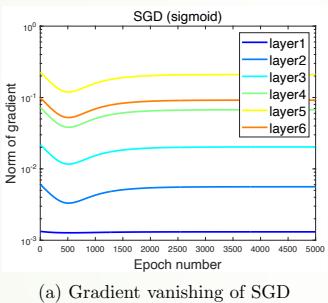

- ▶ Sepp Hochreiter; Jürgen Schmidhuber (1997). "Long short-term memory". *Neural Computation*. 9 (8): 1735–1780. (<https://www.bioinf.jku.at/publications/older/2604.pdf>)
- ▶ BP can not train deep networks due to gradient vanishing problem etc.
- ▶ Introduction of **short path** to train deep networks without vanishing gradient problem.
- ▶ This idea will come back to Convolutional Networks as **ResNet** in 2015.

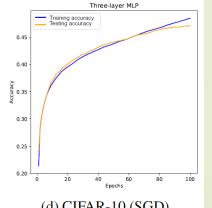

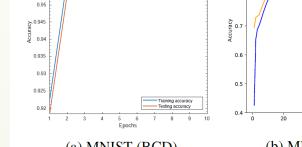

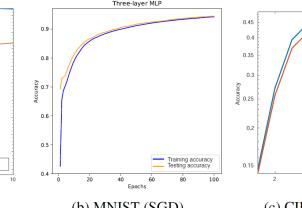

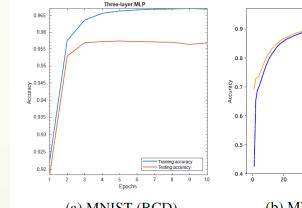

# SGD vs. ADMM/BCD

- ▶ Stochastic Gradient Descent (SGD) suffers from the well-known *gradient vanishing issue* in deep learning
- ▶ ADMM/BCD may alleviate gradient vanishing

- High epoch efficiency of BCD at early stage

# Notes on Algorithms

- ▶ Gradient descent (back propagation) can be derived via Lagrangian multiplier method [LeCun 1988, <http://yann.lecun.com/exdb/publis/pdf/lecun-88.pdf>]
- ▶ **ADMM** is alternative primal-dual method via **Augmented Lagrangian** multipliers [Zeng-Lin-Y.-Zhou, JMLR 2021]
- ▶ **BCD** (Block-Coordinate-Descent) **drops** the dual update in Augmented Lagrangian multipliers [Zeng-Lau-Lin-Y., ICML 2019]
- ▶ Global convergence to KKT points from arbitrary initialization can be established with the aid of **Kurdyka-Łojasiewicz** framework.

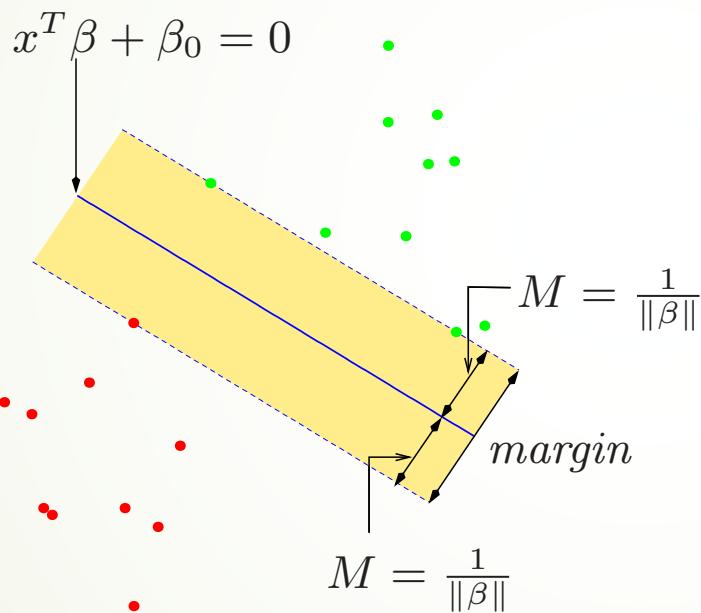

$$\begin{aligned} & \underset{\mathcal{W}, \mathcal{V}}{\text{minimize}} \quad \frac{1}{2} \|V_N - Y\|_F^2 + \frac{\lambda}{2} \sum_{i=1}^N \|W_i\|_F^2 \\ & \text{subject to} \quad V_i = \sigma(W_i V_{i-1}), \quad i = 1, \dots, N-1, \quad V_N = W_N V_{N-1}, \end{aligned}$$

**Augmented Lagrangian** function:

Lagrangian multiplier  $\Lambda_i$

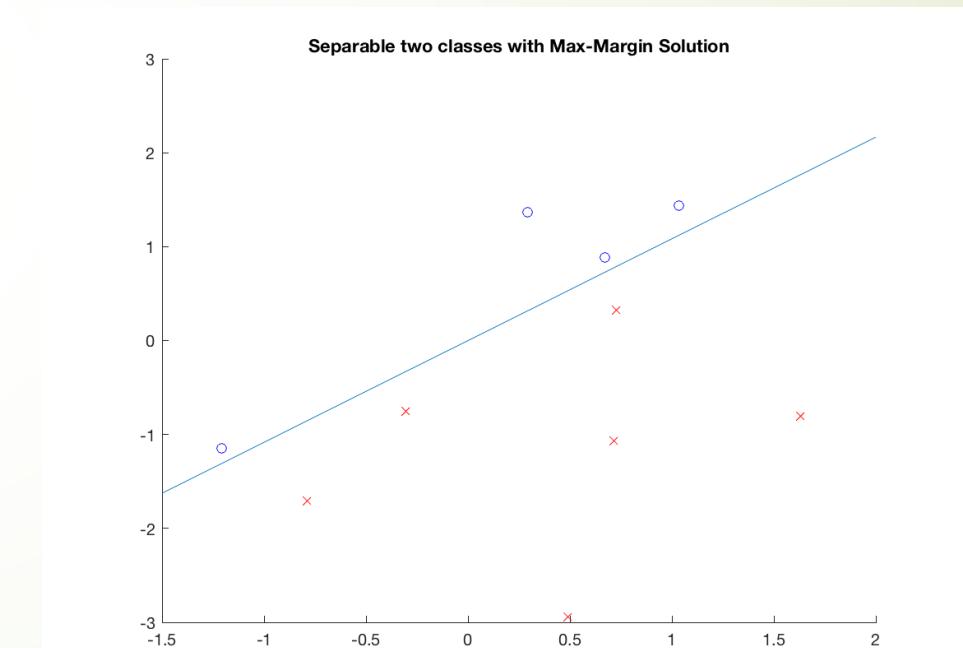

$$\begin{aligned} \mathcal{L}(\mathcal{W}, \mathcal{V}, \{\Lambda_i\}_{i=1}^N) := & \frac{1}{2} \|V_N - Y\|_F^2 + \frac{\lambda}{2} \sum_{i=1}^N \|W_i\|_F^2 \\ & + \sum_{i=1}^{N-1} \left( \frac{\beta_i}{2} \|\sigma(W_i V_{i-1}) - V_i\|_F^2 + \langle \Lambda_i, \sigma(W_i V_{i-1}) - V_i \rangle \right) \\ & + \frac{\beta_N}{2} \|W_N V_{N-1} - V_N\|_F^2 + \langle \Lambda_N, W_N V_{N-1} - V_N \rangle, \end{aligned}$$

# Support Vector Machine (Max-Margin Classifier)

Vladimir Vapnik, 1994

$$\begin{aligned} & \text{minimize}_{\beta_0, \beta_1, \dots, \beta_p} \|\beta\|^2 := \sum_j \beta_j^2 \\ & \text{subject to } y_i(\beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip}) \geq 1 \text{ for all } i \end{aligned}$$

Convex optimization + Reproducing Kernel Hilbert Spaces (Grace Wahba etc.)

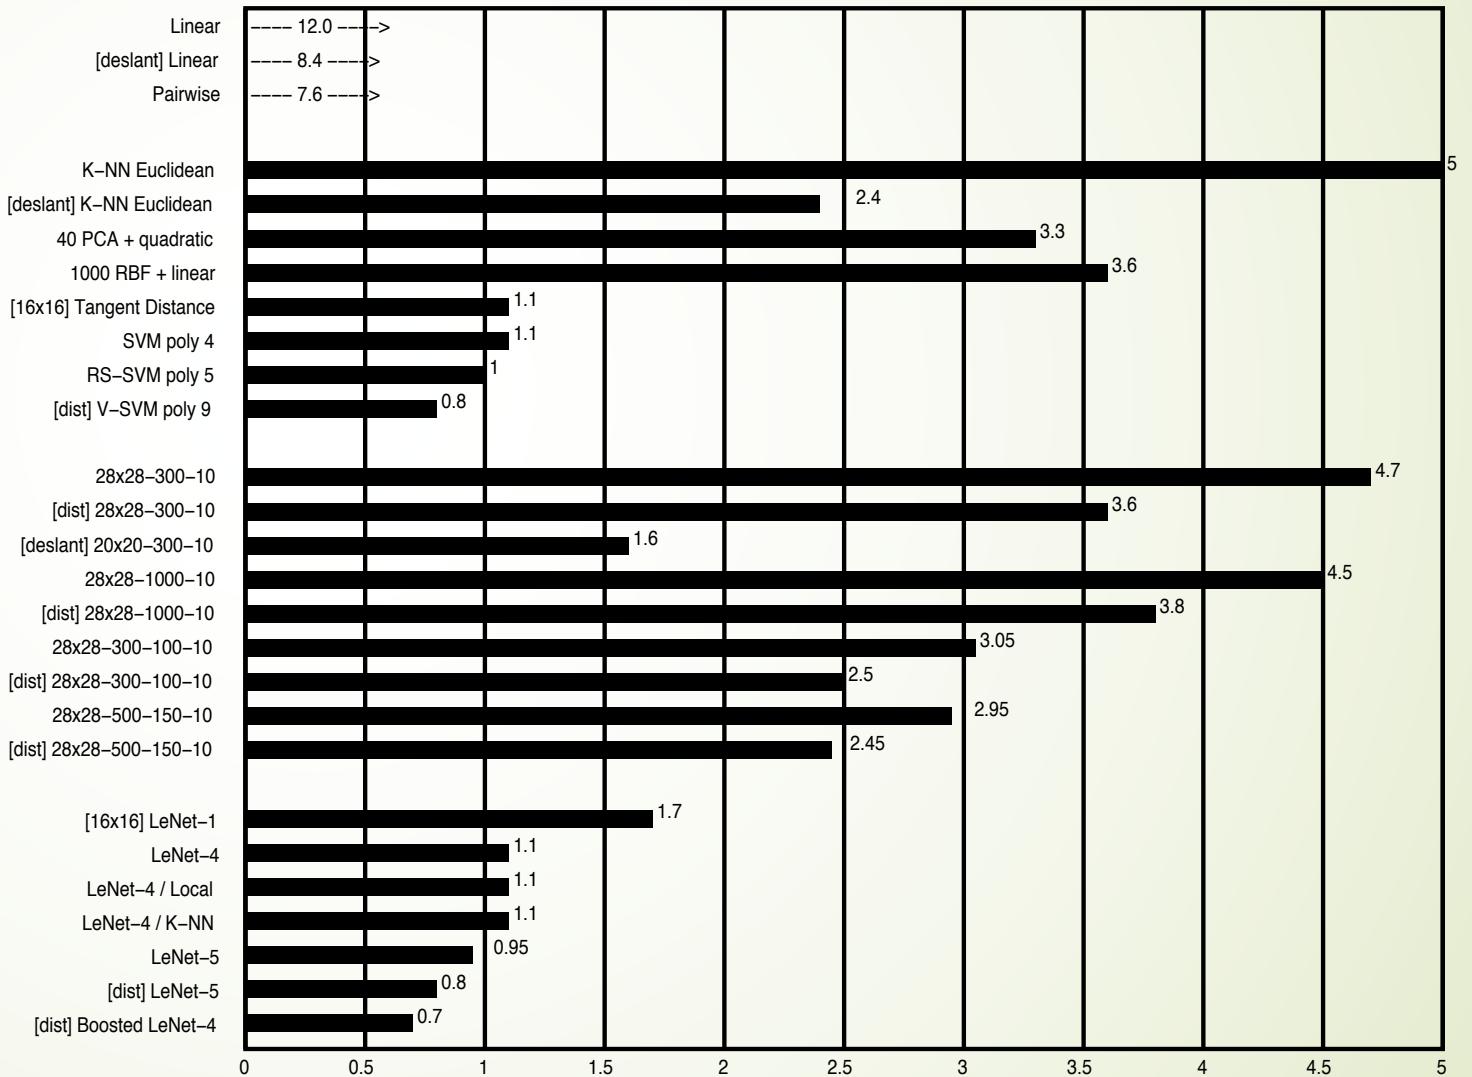

# MNIST Challenge Test Error: SVM vs. CNN

## LeCun et al. 1998

Simple SVM performs as well as Multilayer Convolutional Neural Networks which need careful tuning (LeNets)

Second dark era for NN:  
2000s

# LeNet

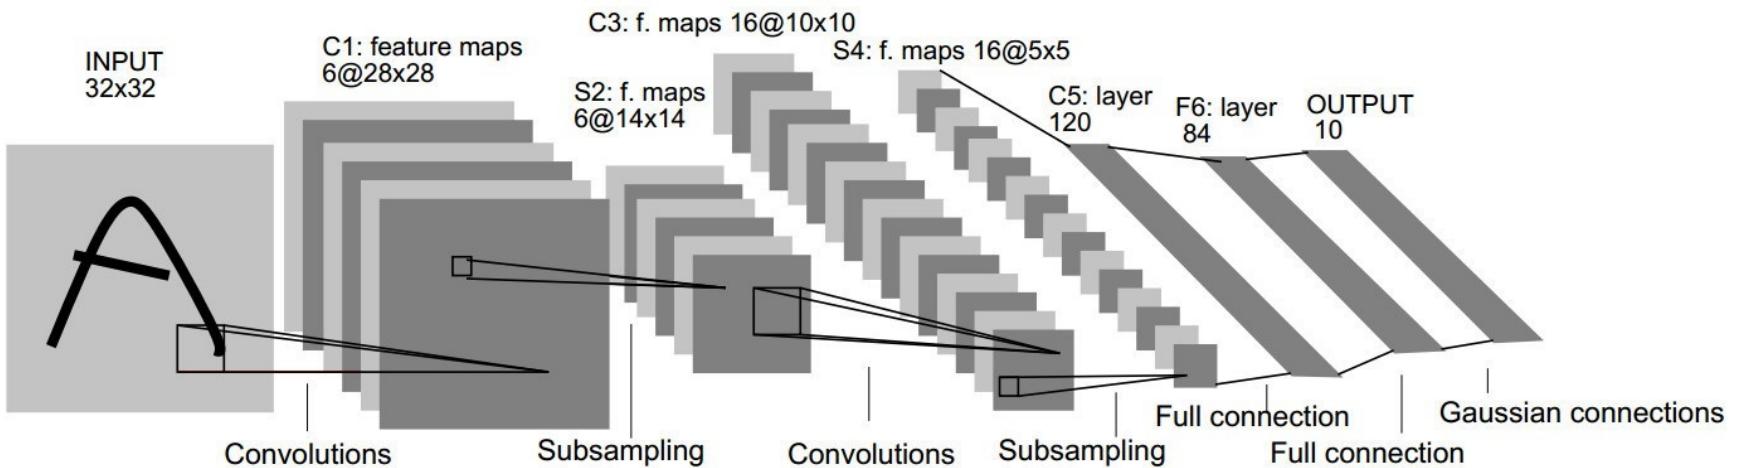

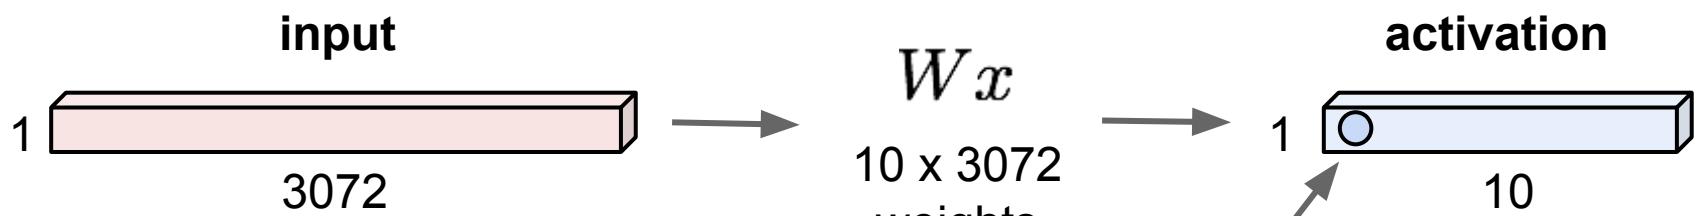

Fig. 2. Architecture of LeNet-5, a Convolutional Neural Network, here for digits recognition. Each plane is a feature map, i.e. a set of units whose weights are constrained to be identical.

<http://blog.csdn.net/Chenyukuai6625>

- **Y. LeCun, L. Bottou, Y. Bengio, and P. Haffner.** Gradient-based learning applied to document recognition. *Proceedings of the IEEE*, november 1998.

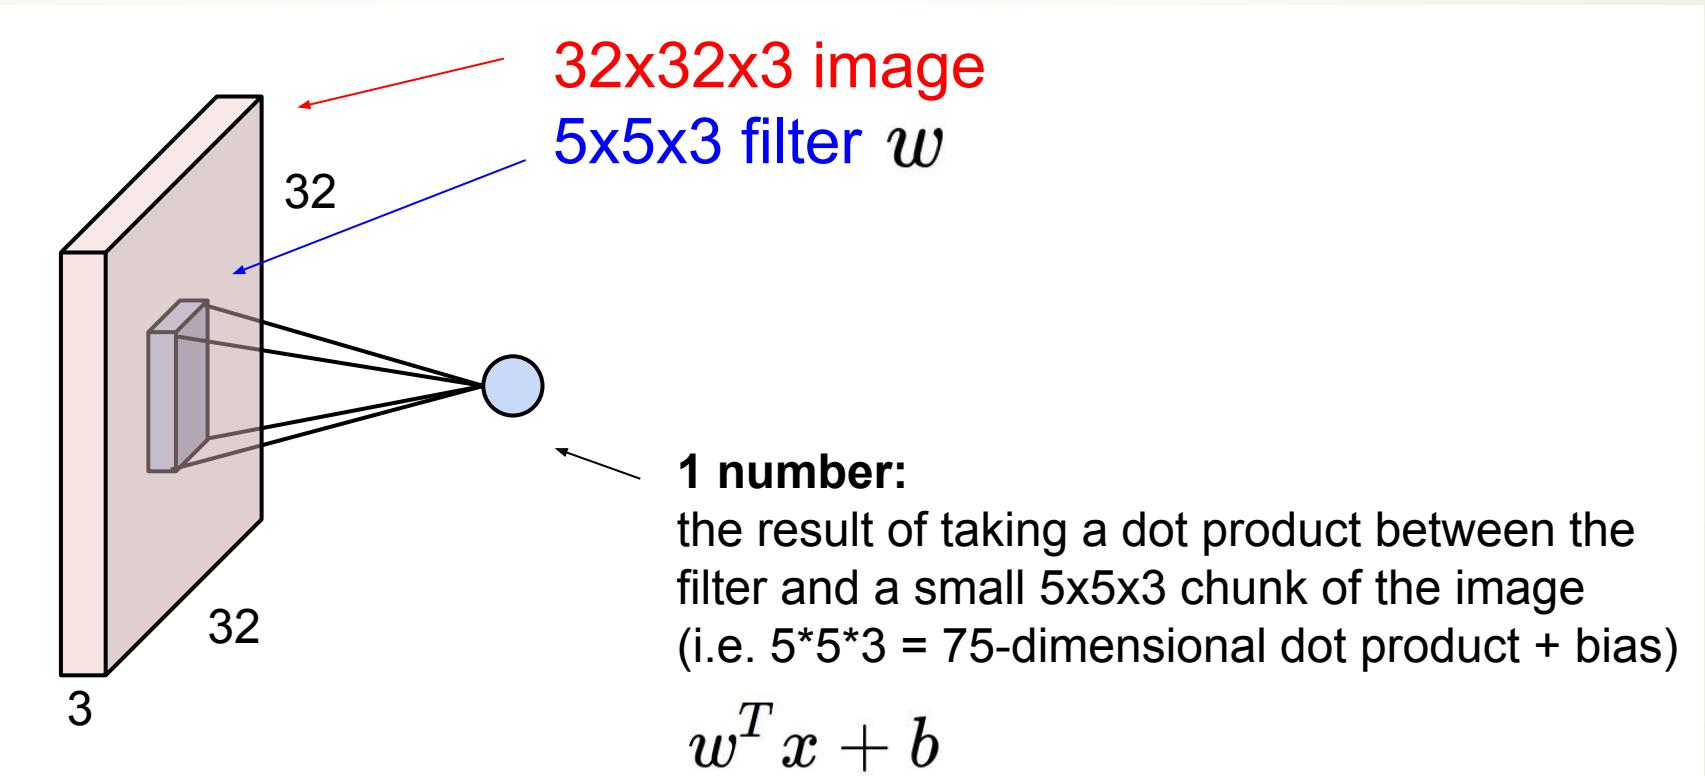

# Fully Connected Layer

32x32x3 image -> stretch to 3072 x 1

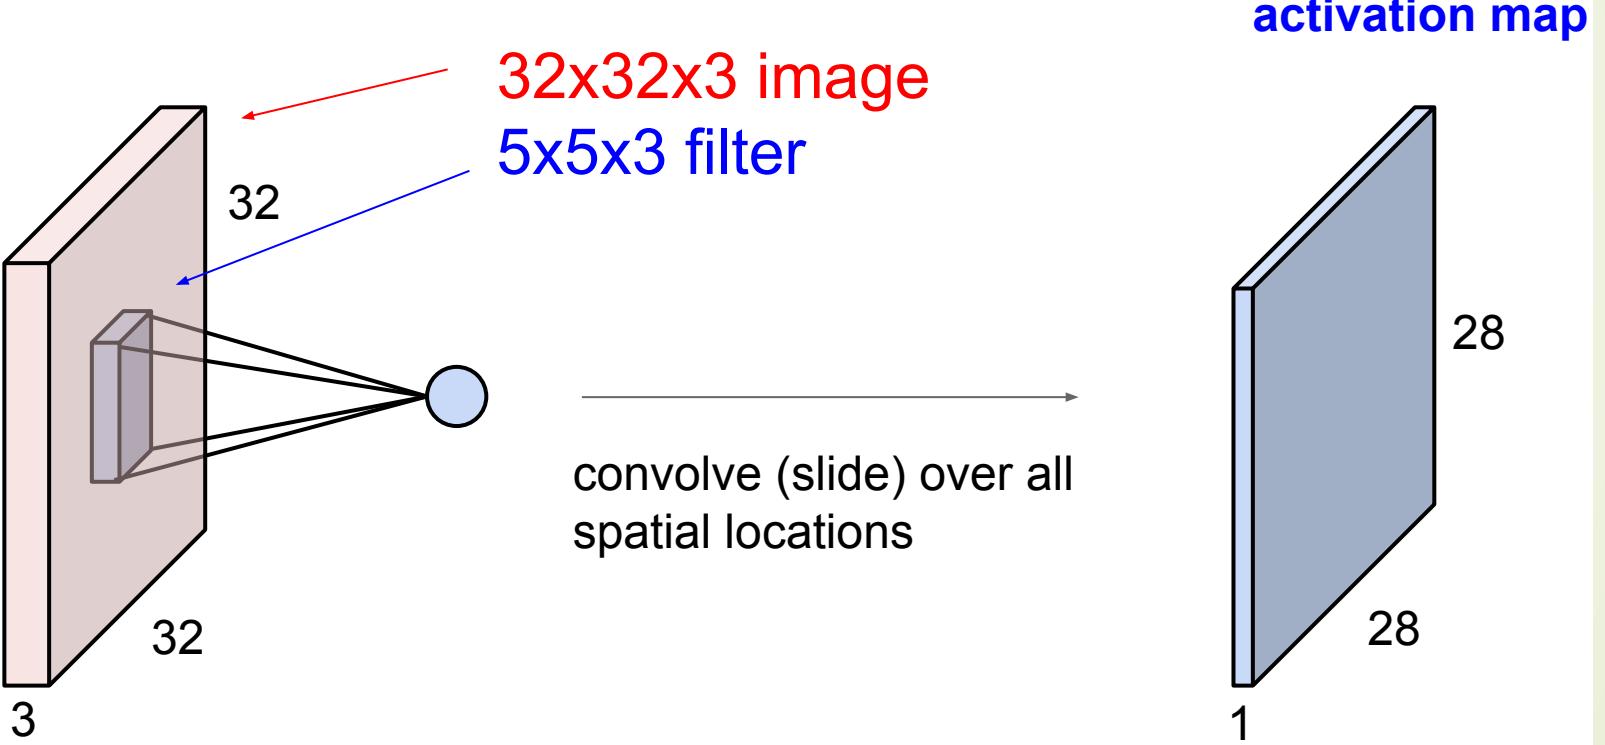

**1 number:**  
the result of taking a dot product  
between a row of  $W$  and the input  
(a 3072-dimensional dot product)

# Convolution

# Convolution Layer: a first (blue) filter

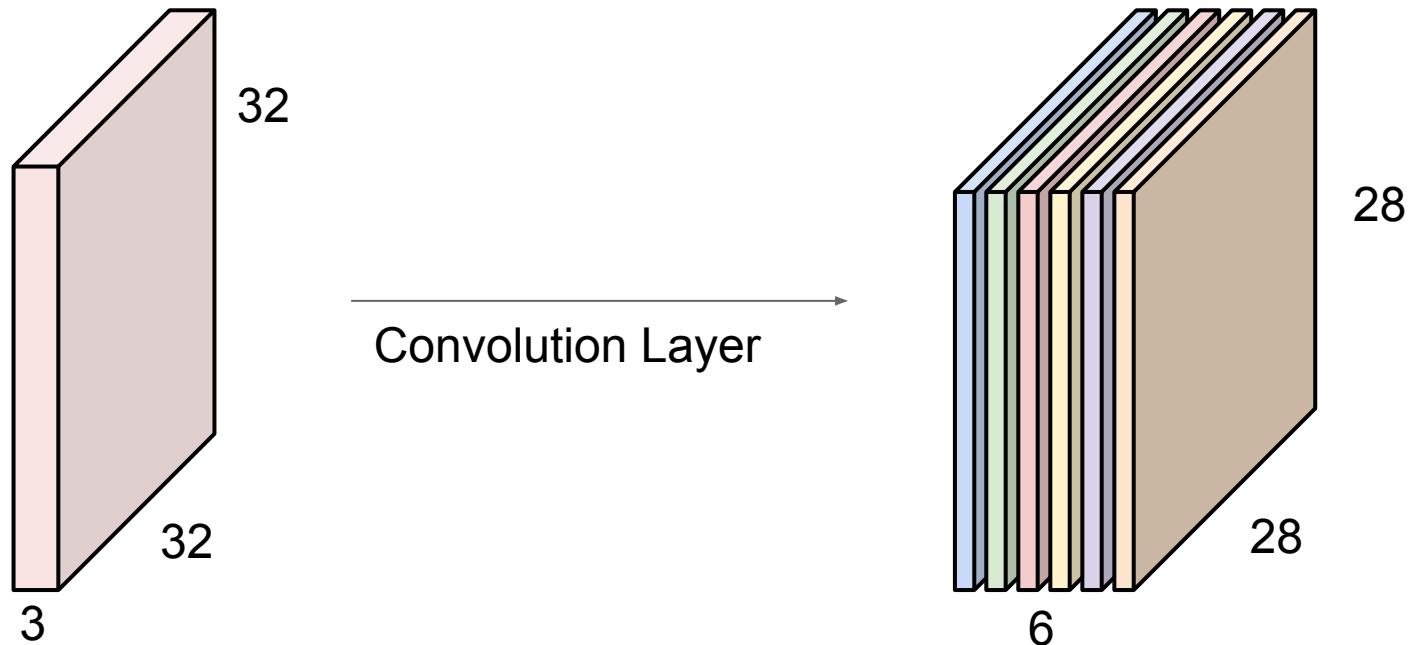

# Convolution Layer: a second (green) filter

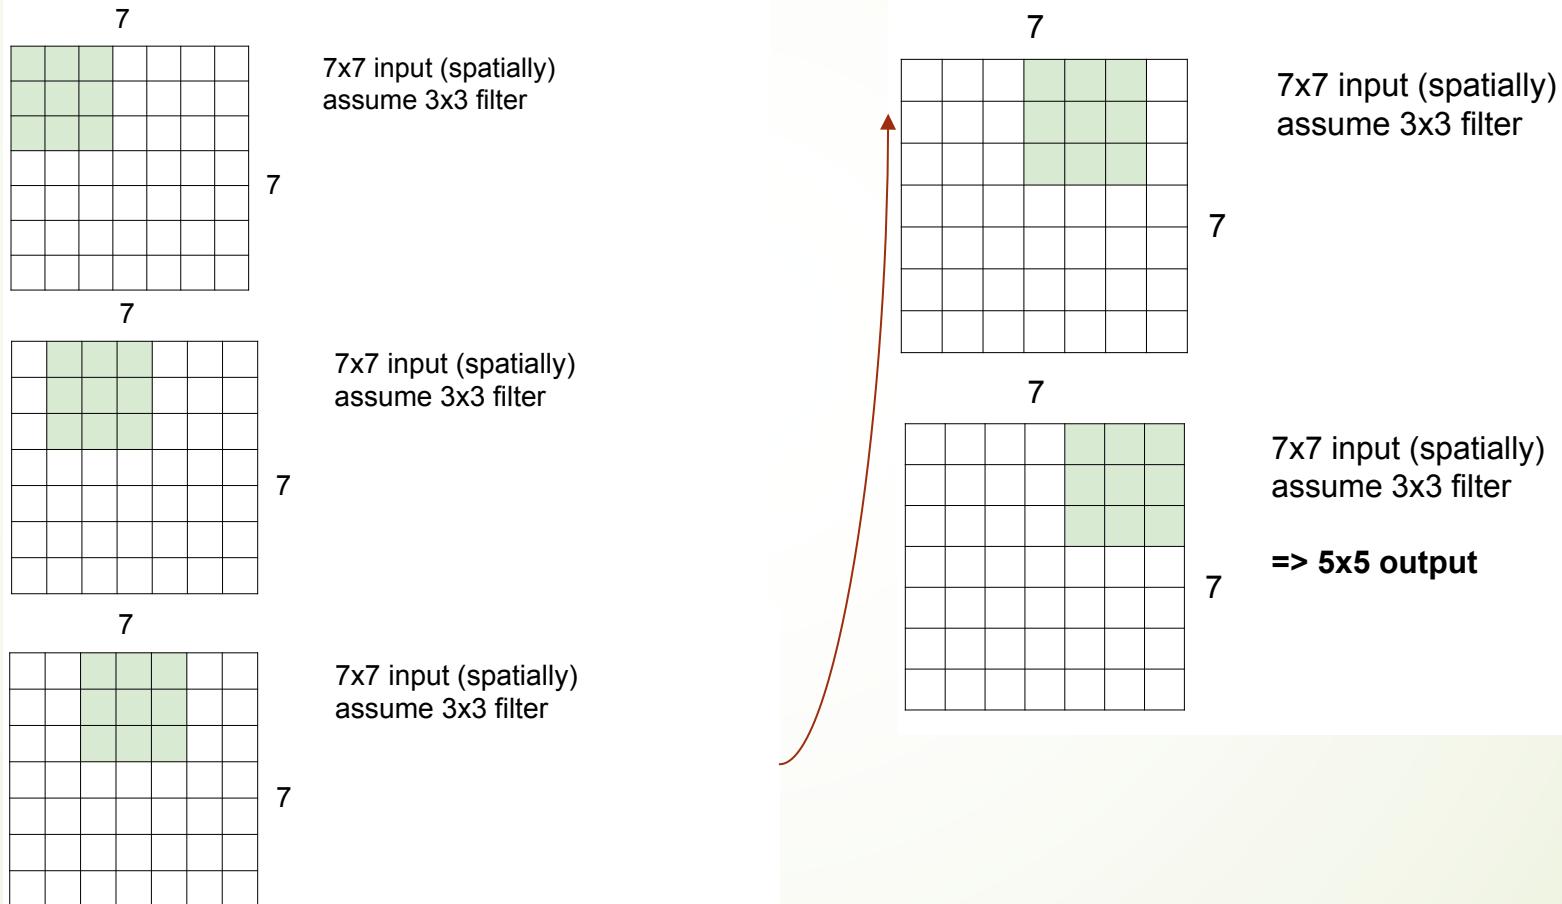

# Convolution Layer

For example, if we had 6 5x5 filters, we'll get 6 separate activation maps:

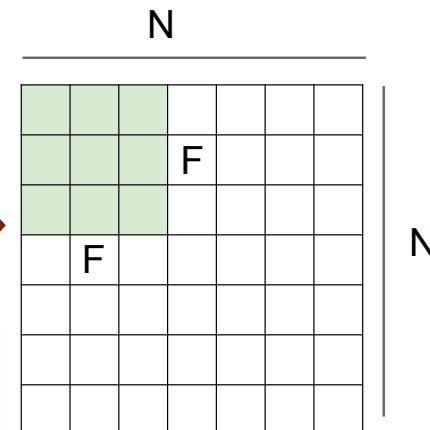

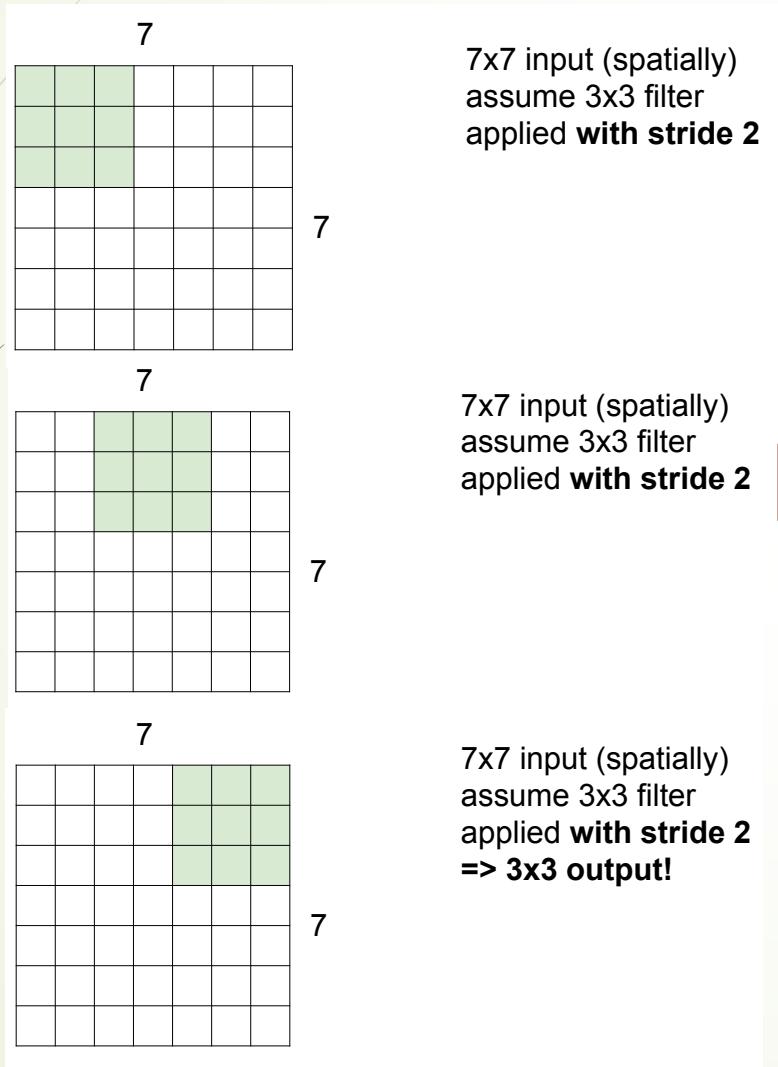

We stack these up to get a “new image” of size  $28 \times 28 \times 6$ !

# A Closer Look at Convolution: stride=1

# A Closer Look at Convolution: stride=2

Output size:  
 $(N - F) / \text{stride} + 1$

e.g.  $N = 7$ ,  $F = 3$ :  
stride 1 =>  $(7 - 3)/1 + 1 = 5$   
stride 2 =>  $(7 - 3)/2 + 1 = 3$   
stride 3 =>  $(7 - 3)/3 + 1 = 2.33 \vdots$

# A Closer Look at Convolution: Padding

0	0	0	0	0	0			
0								
0								
0								
0								

e.g. input 7x7

**3x3 filter, applied with stride 1**

**pad with 1 pixel border => what is the output?**

**7x7 output!**

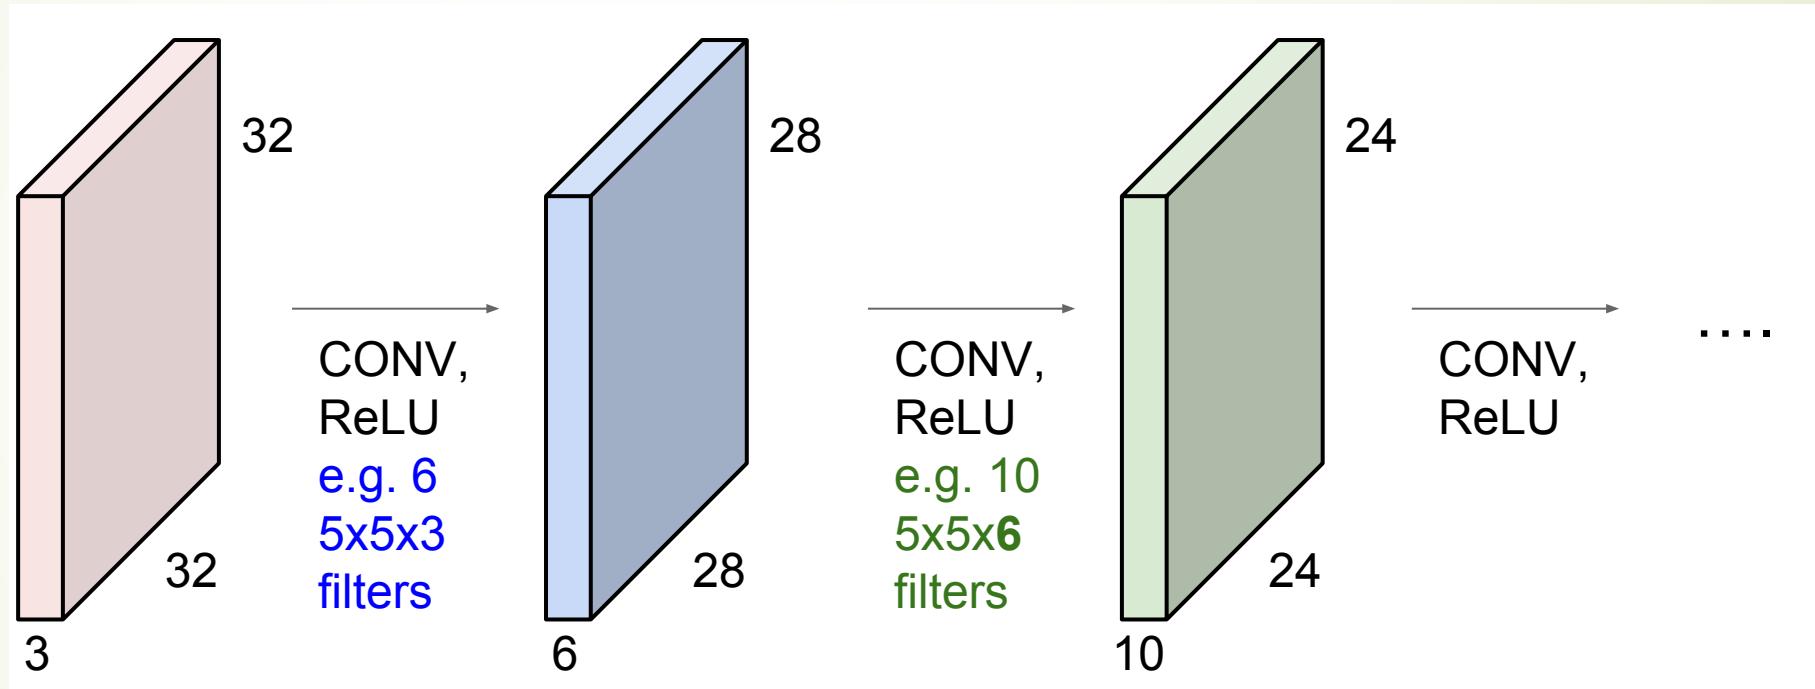

in general, common to see CONV layers with stride 1, filters of size FxF, and zero-padding with  $(F-1)/2$ . (will preserve size spatially)

e.g.  $F = 3 \Rightarrow$  zero pad with 1

$F = 5 \Rightarrow$  zero pad with 2

$F = 7 \Rightarrow$  zero pad with 3

# ConvNet:

Stride = 1  
Padding = 0

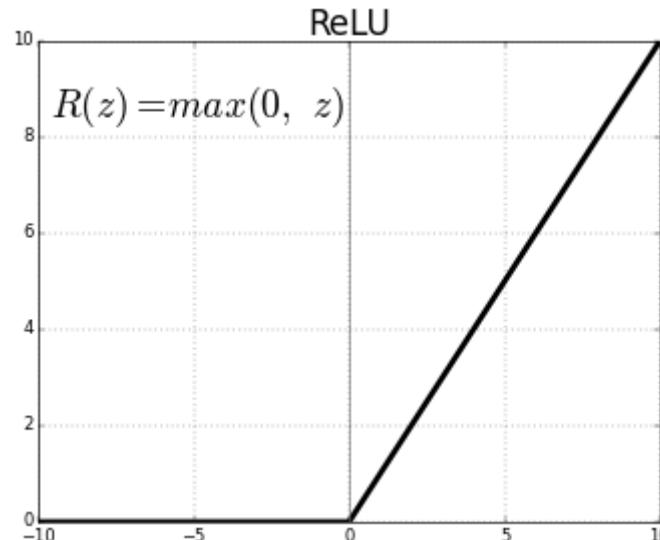

# Formula: `NewImageSize = floor((ImageSize - Filter + 2*Padding)/Stride + 1)`

**Summary.** To summarize, the Conv Layer:

- Accepts a volume of size  $W_1 \times H_1 \times D_1$
- Requires four hyperparameters:
  - Number of filters  $K$ ,
  - their spatial extent  $F$ ,
  - the stride  $S$ ,
  - the amount of zero padding  $P$ .
- Produces a volume of size  $W_2 \times H_2 \times D_2$  where:
  - $W_2 = (W_1 - F + 2P)/S + 1$
  - $H_2 = (H_1 - F + 2P)/S + 1$  (i.e. width and height are computed equally by symmetry)
  - $D_2 = K$
- With parameter sharing, it introduces  $F \cdot F \cdot D_1$  weights per filter, for a total of  $(F \cdot F \cdot D_1) \cdot K$  weights and  $K$  biases.
- In the output volume, the  $d$ -th depth slice (of size  $W_2 \times H_2$ ) is the result of performing a valid convolution of the  $d$ -th filter over the input volume with a stride of  $S$ , and then offset by  $d$ -th bias.

# ReLU

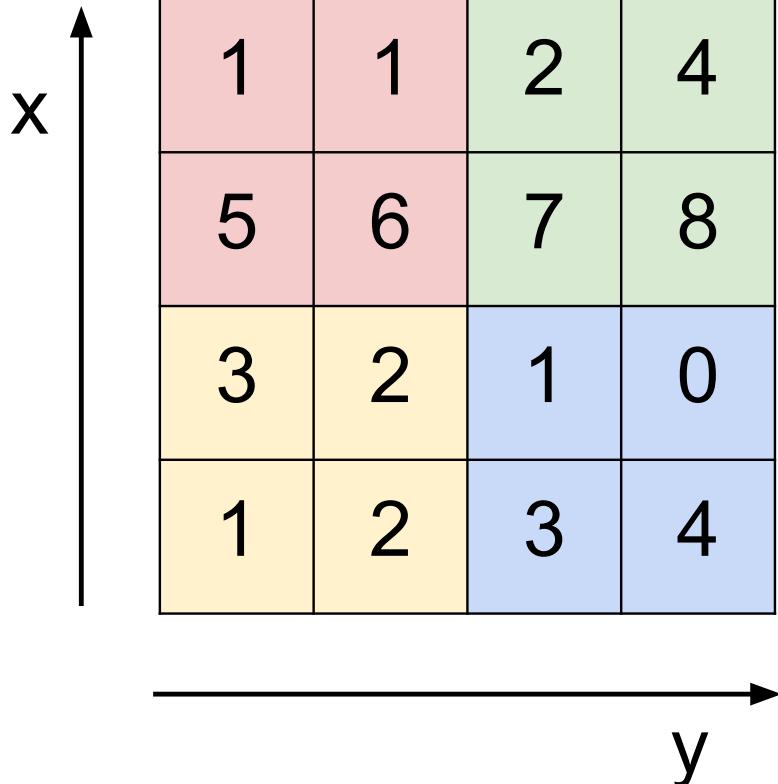

- Non-saturating function and therefore faster convergence when compared to other nonlinearities
- Problem of dying neurons

# GoogLeNet [Szegedy et al., 2014]

- ▶ 22 layers
- ▶ Efficient “Inception” module
- ▶ No FC layers
- ▶ Only 5 million parameters!
- ▶ 12x less than AlexNet
- ▶ ILSVRC’14 classification winner  
(6.7% top 5 error)

Inception module

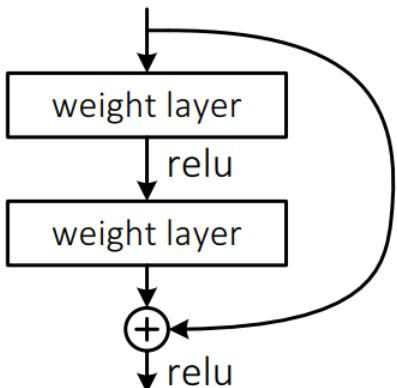

# ResNet (2015) [HGRS-15]

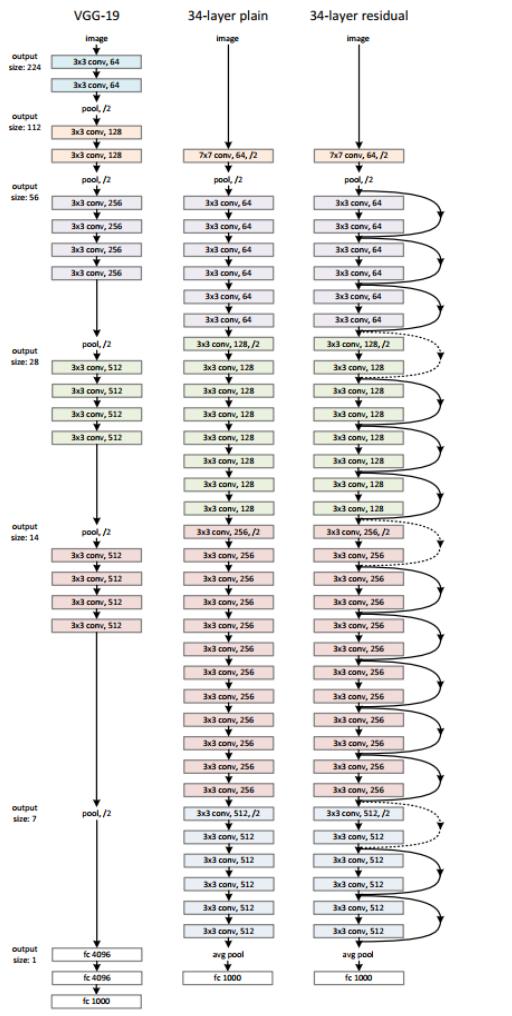

# ILSVRC'15 classification winner (3.57% top 5 error)

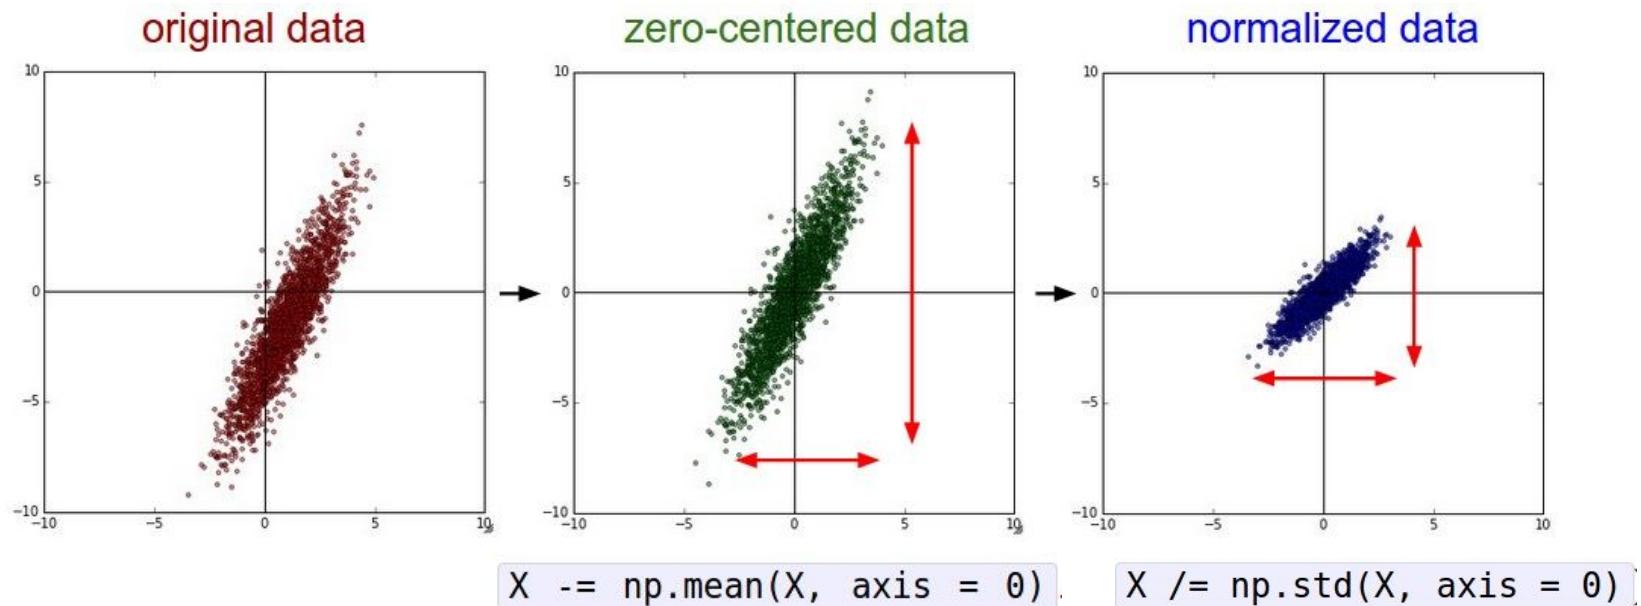

- Solves problem by adding skip connections
  - Very deep: 152 layers
  - No dropout
  - Stride
  - Batch normalization

Source: Deep Residual Learning for Image Recognition

# Batch Normalization

(Assume  $X$  [NxD] is data matrix,  
each example in a row)

# Batch Normalization

---

**Algorithm 2** Batch normalization [Ioffe and Szegedy, 2015]

**Input:** Values of  $x$  over minibatch  $x_1 \dots x_B$ , where  $x$  is a certain channel in a certain feature vector

**Output:** Normalized, scaled and shifted values  $y_1 \dots y_B$

- 
- 1:  $\mu = \frac{1}{B} \sum_{b=1}^B x_b$
  - 2:  $\sigma^2 = \frac{1}{B} \sum_{b=1}^B (x_b - \mu)^2$
  - 3:  $\hat{x}_b = \frac{x_b - \mu}{\sqrt{\sigma^2 + \epsilon}}$
  - 4:  $y_b = \gamma \hat{x}_b + \beta$
- 

- Accelerates training and makes initialization less sensitive
- Zero mean and unit variance feature vectors

# BatchNorm at Test

**Input:** Values of  $x$  over a mini-batch:  $\mathcal{B} = \{x_1 \dots m\}$ ;  
Parameters to be learned:  $\gamma, \beta$

**Output:**  $\{y_i = \text{BN}_{\gamma, \beta}(x_i)\}$

$$\mu_{\mathcal{B}} \leftarrow \frac{1}{m} \sum_{i=1}^m x_i \quad // \text{mini-batch mean}$$

$$\sigma_{\mathcal{B}}^2 \leftarrow \frac{1}{m} \sum_{i=1}^m (x_i - \mu_{\mathcal{B}})^2 \quad // \text{mini-batch variance}$$

$$\hat{x}_i \leftarrow \frac{x_i - \mu_{\mathcal{B}}}{\sqrt{\sigma_{\mathcal{B}}^2 + \epsilon}} \quad // \text{normalize}$$

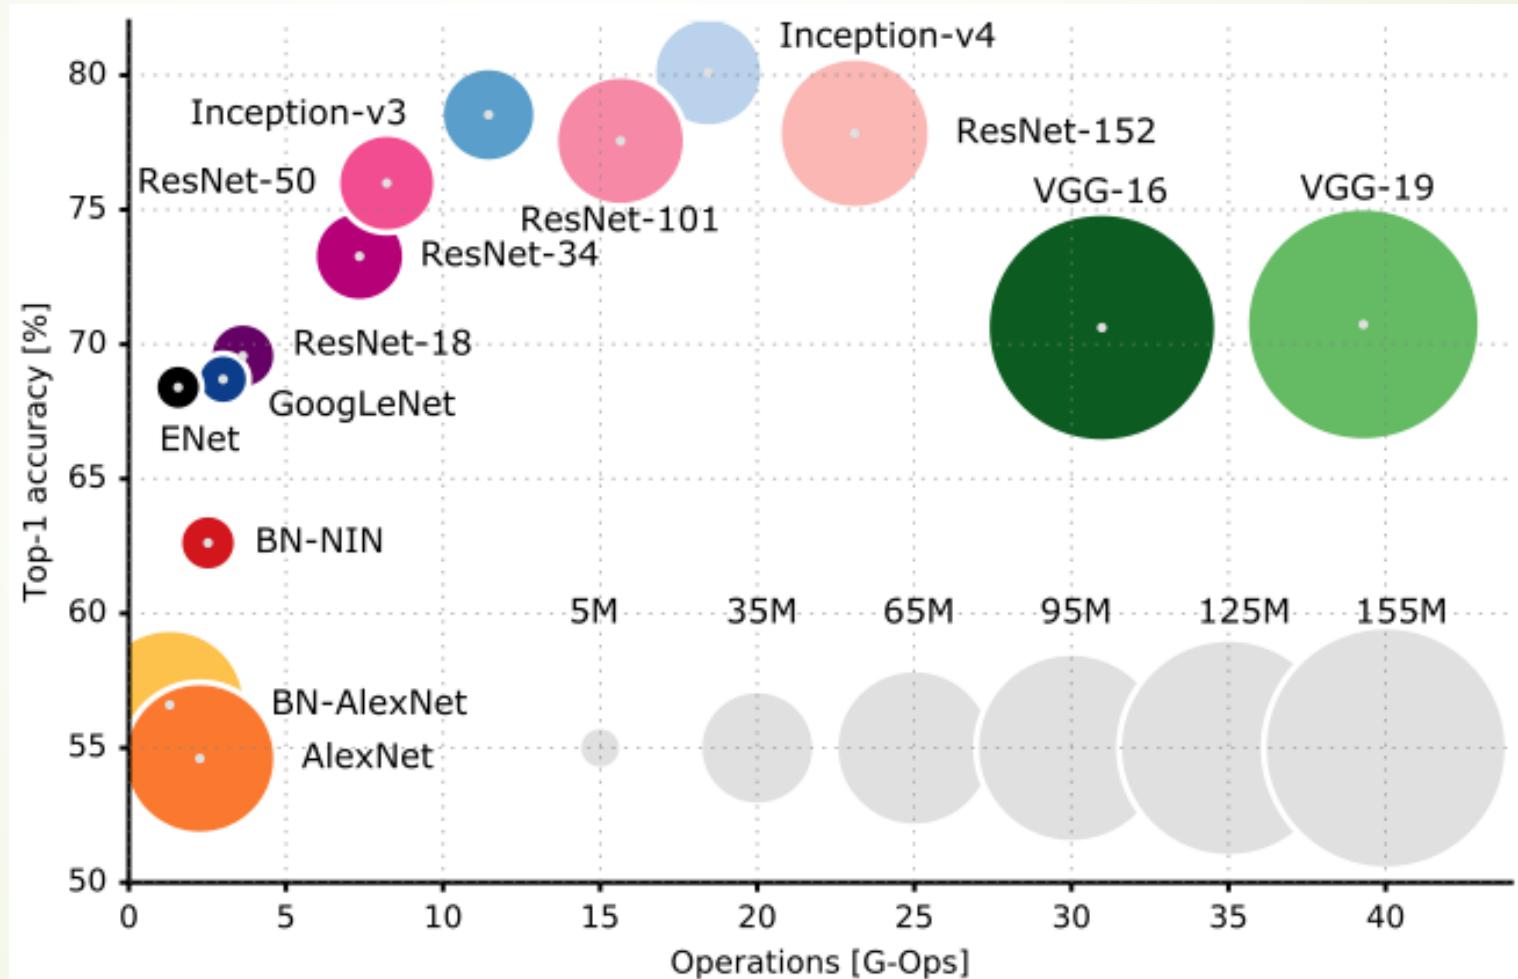

$$y_i \leftarrow \gamma \hat{x}_i + \beta \equiv \text{BN}_{\gamma, \beta}(x_i) \quad // \text{scale and shift}$$

**Note: at test time BatchNorm layer functions differently:**

The mean/std are not computed based on the batch. Instead, a single fixed empirical mean of activations during training is used.

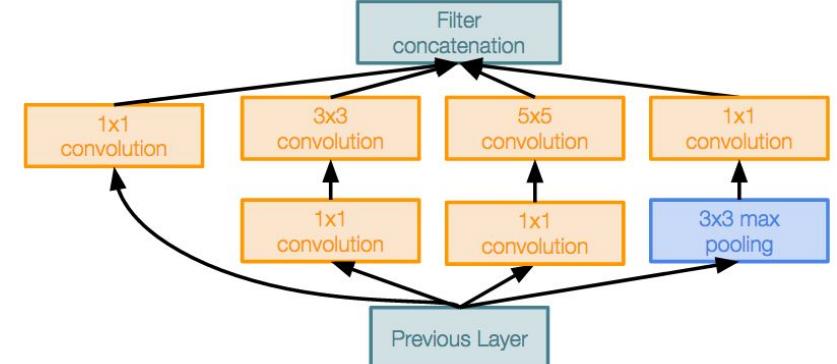

(e.g. can be estimated during training with running averages)

# Complexity vs. Accuracy of Different Networks

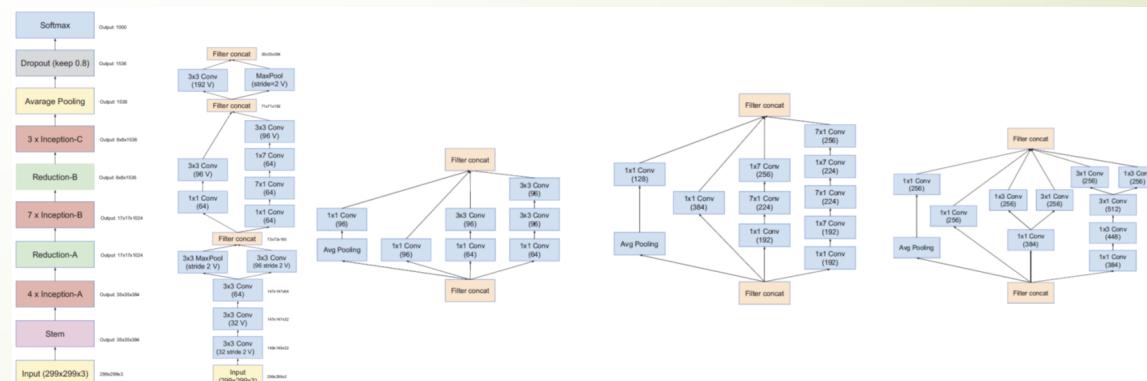

# Inception-v4 = ResNet + Inception

- ▶ “**Inception**” module:
  - ▶ Introduced by Szegedy et al., 2014 in **GoogLeNet**
  - ▶ ILSVRC’14 classification winner (6.7% top 5 error)
- ▶ Apply parallel filter operations on the input from previous layer:
  - ▶ Dimensionality reduction ( $1 \times 1$  conv)
  - ▶ Multiple receptive field sizes for convolution ( $1 \times 1$ ,  $3 \times 3$ ,  $5 \times 5$ )
  - ▶ Pooling operation ( $3 \times 3$ )
- ▶ Concatenate all filter outputs together depth-wise

# Transfer Learning: Feature Extraction and Fine Tuning

# Transfer Learning?

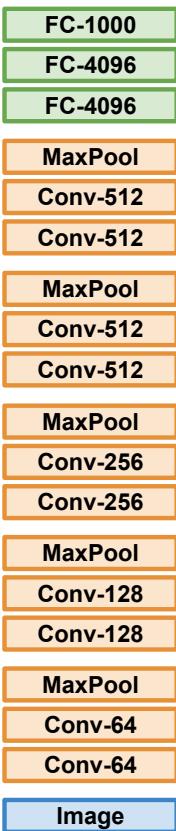

- Filters learned in first layers of a network are transferable from one task to another
- When solving another problem, no need to retrain the lower layers, just fine tune upper ones
- Is this simply due to the large amount of images in ImageNet?
- Does solving many classification problems simultaneously result in features that are more easily transferable?
- Does this imply filters can be learned in unsupervised manner?
- Can we characterize filters mathematically?

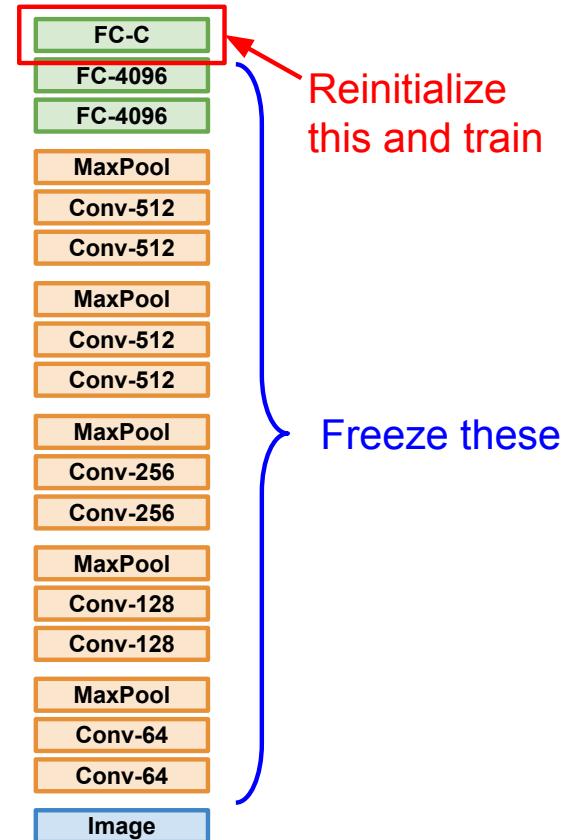

Donahue et al, "DeCAF: A Deep Convolutional Activation Feature for Generic Visual Recognition", ICML 2014  
Razavian et al, "CNN Features Off-the-Shelf: An Astounding Baseline for Recognition", CVPR Workshops 2014

# Transfer Learning with CNNs

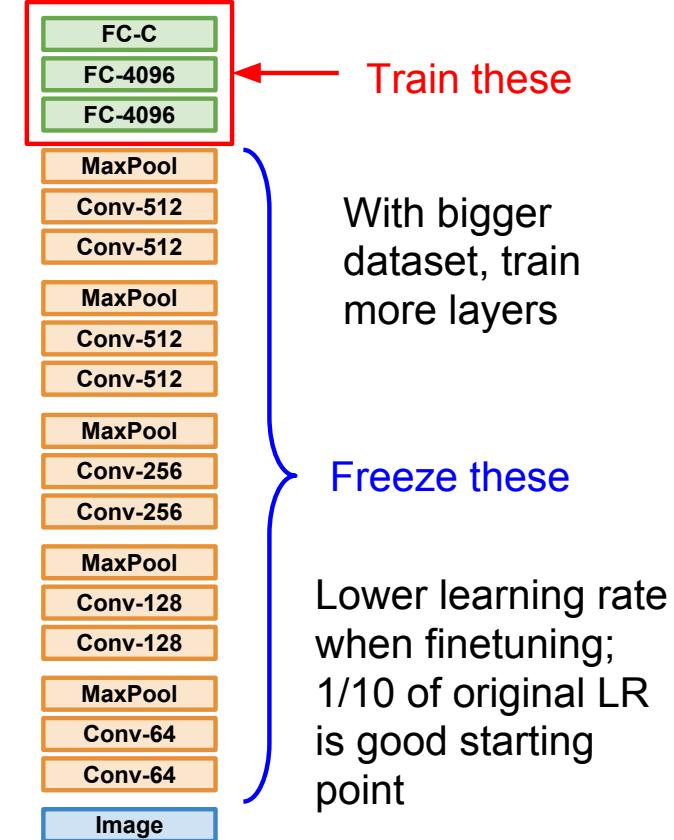

## 1. Train on Imagenet

## 2. Small Dataset (C classes)

## 3. Bigger dataset

More specific

More generic

	<b>very similar dataset</b>	<b>very different dataset</b>
<b>very little data</b>	Use Linear Classifier on top layer	You're in trouble... Try linear classifier from different stages
<b>quite a lot of data</b>	Finetune a few layers	Finetune a larger number of layers

# Summary

- ▶ Feature Extraction vs. Fine-Tuning:
  - ▶ Feature extraction usually refers to freeze the bottom (early layers) and retrain the top (last) layer
  - ▶ Fine-Tuning usually refers to retrain the last few layers or the whole network initialized from pretrained parameters
  - ▶ They are both called transfer learning
- ▶ Jupyter notebook examples with pytorch:
  - ▶ [https://github.com/aifin-hkust/aifin-hkust.github.io/blob/master/2020/notebook/finetuning\\_resnet.ipynb](https://github.com/aifin-hkust/aifin-hkust.github.io/blob/master/2020/notebook/finetuning_resnet.ipynb)

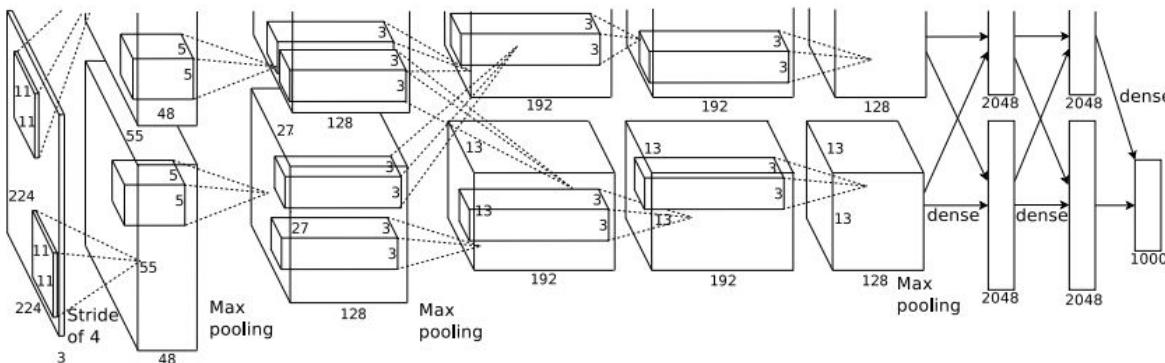

# Visualizing Convolutional Networks

# Understanding intermediate neurons?

Input Image:  
3 x 224 x 224

What are the intermediate features looking for?

Class Scores:  
1000 numbers

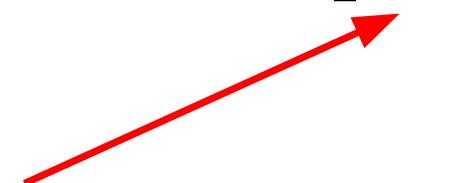

# Visualizing CNN Features: Gradient Ascent

- **Gradient ascent:** Generate a synthetic image that maximally activates a neuron

$$I^* = \arg \max_I f(I) + R(I)$$

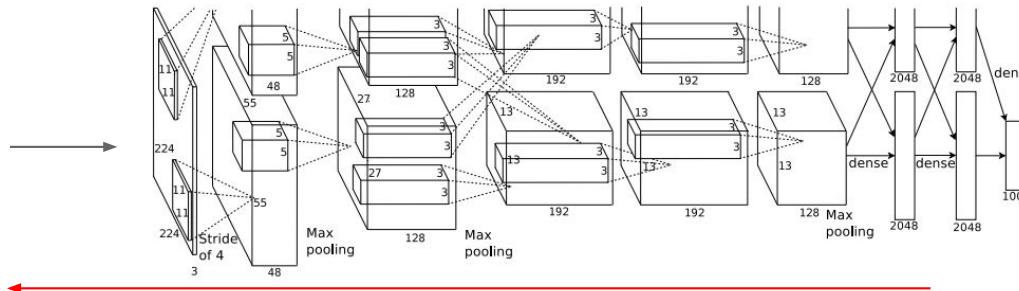

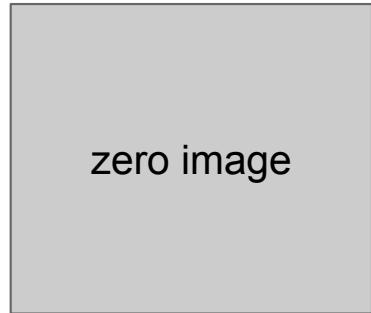

Neuron value

Natural image regularizer

# Visualizing CNN Features: Gradient Ascent

1. Initialize image to zeros

Repeat:

2. Forward image to compute current scores
3. Backprop to get gradient of neuron value with respect to image pixels
4. Make a small update to the image

$$\arg \max_I S_c(I) - \lambda \|I\|_2^2$$

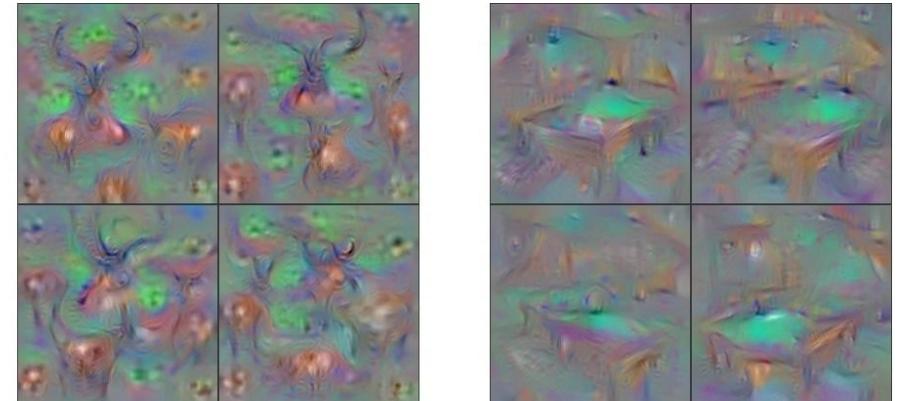

score for class c (before Softmax)

# Visualizing CNN Features: Gradient Ascent

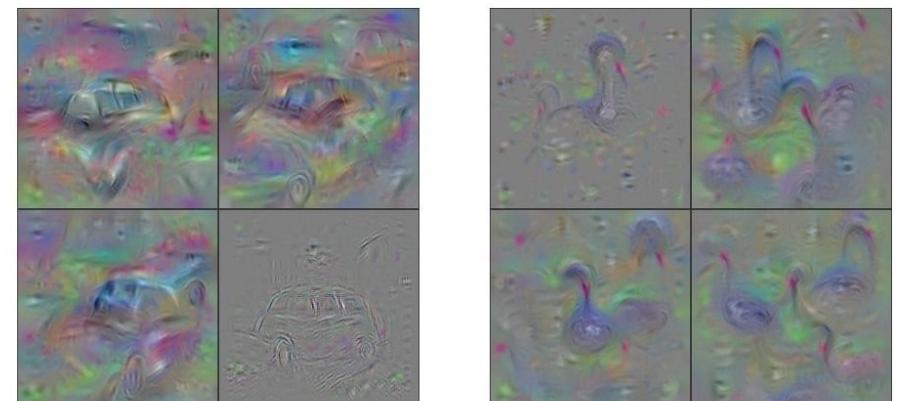

$$\arg \max_I S_c(I) - \lambda \|I\|_2^2$$

Better regularizer: Penalize L2 norm of image; also during optimization periodically

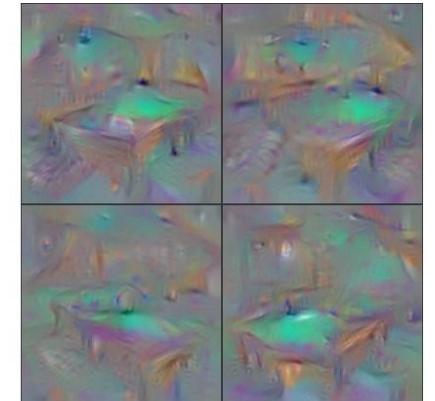

- (1) Gaussian blur image
- (2) Clip pixels with small values to 0
- (3) Clip pixels with small gradients to 0

Springenberg et al, "Striving for Simplicity: The All Convolutional Net", ICLR Workshop 2015  
Figure copyright Jost Tobias Springenberg, Alexey Dosovitskiy, Thomas Brox, Martin Riedmiller, 2015; reproduced with permission.

# DeepDream: amplifying features

Rather than synthesizing an image to maximize a specific neuron, instead try to **amplify** the neuron activations at some layer in the network

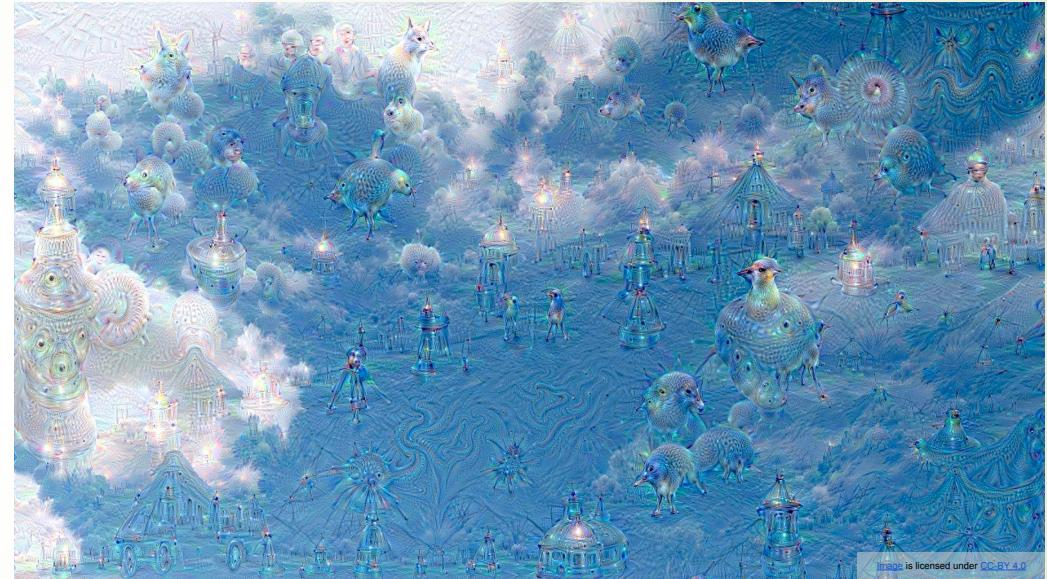

Choose an image and a layer in a CNN; repeat:

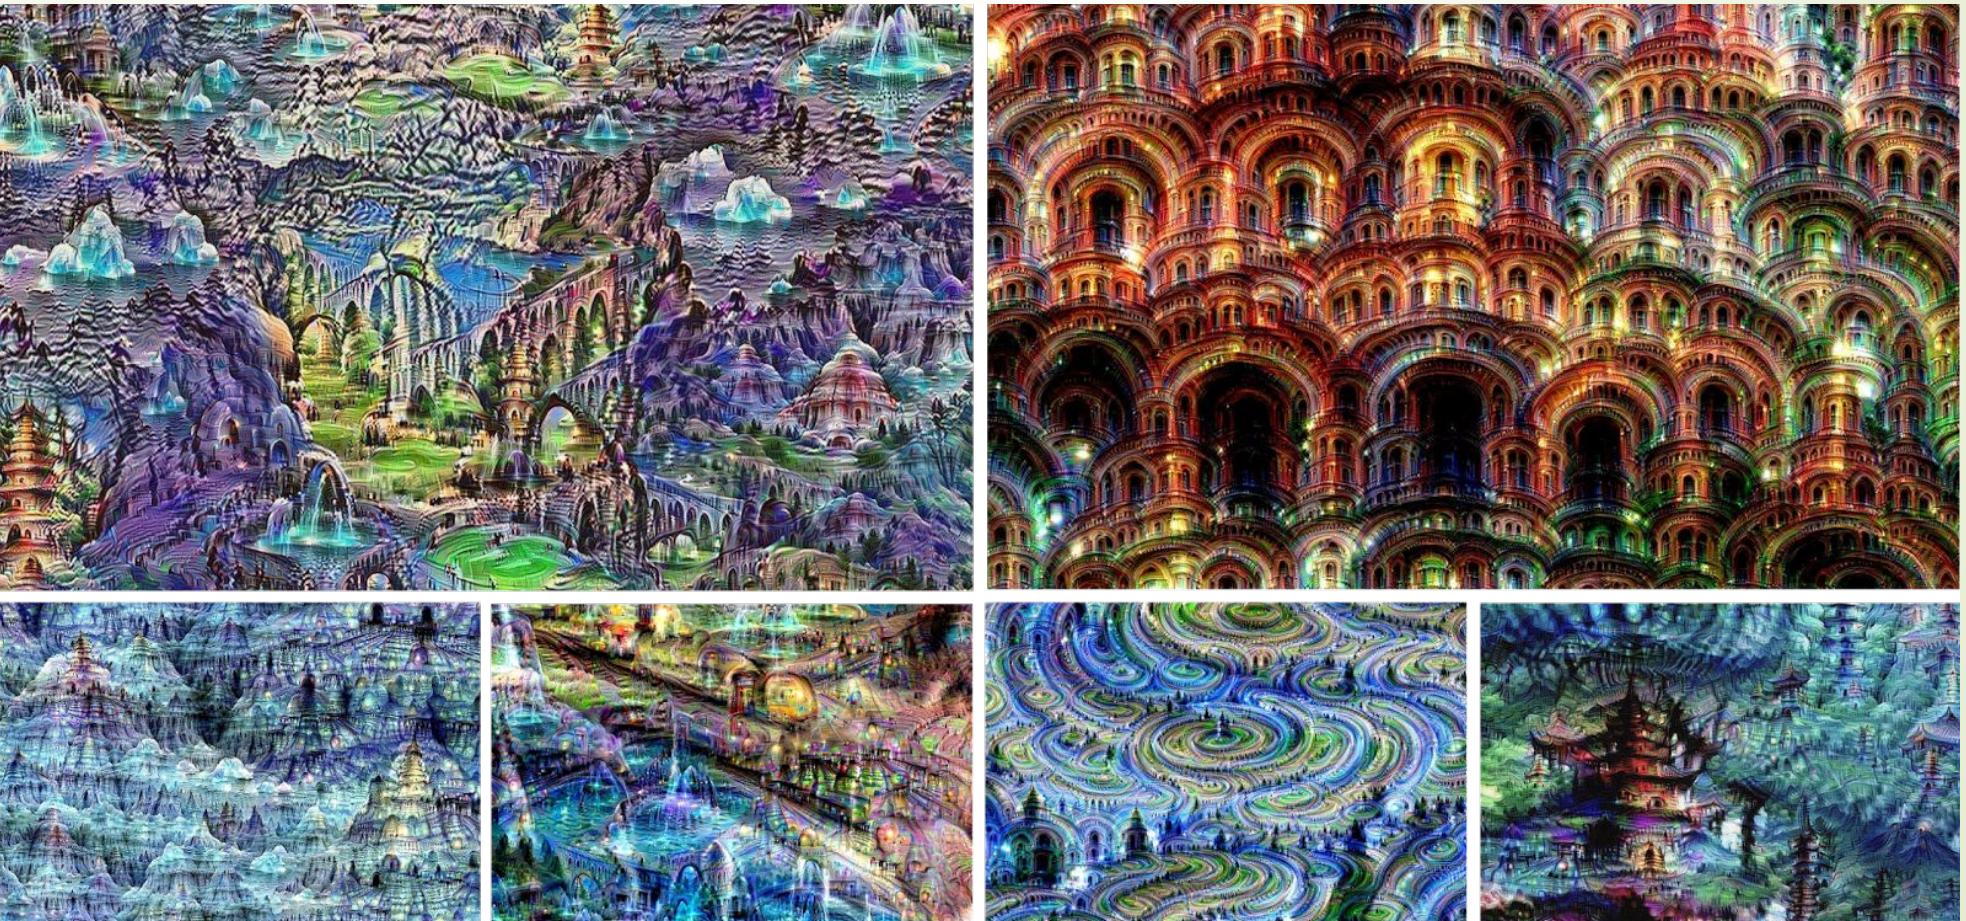

1. Forward: compute activations at chosen layer
2. Set gradient of chosen layer *equal to its activation*
3. Backward: Compute gradient on image
4. Update image

Equivalent to:  
 $I^* = \arg \max_I \sum_i f_i(I)^2$

# Style-Content Feature Extraction

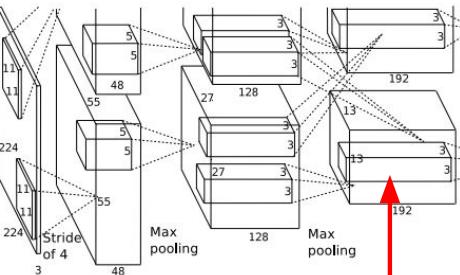

# Style Features as Second Order Statistics

# Gram Matrix as Style Features

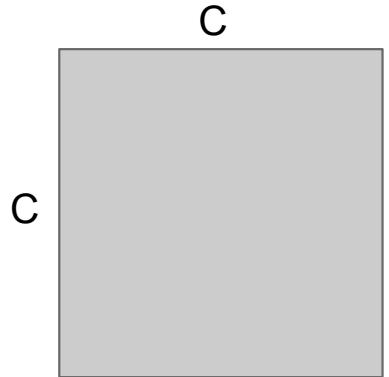

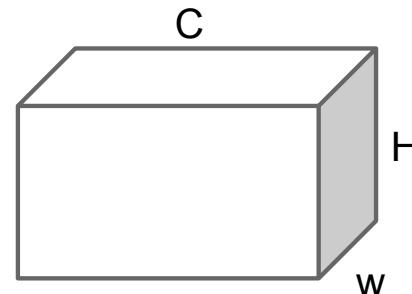

This image is in the public domain.

Each layer of CNN gives  $C \times H \times W$  tensor of features;  $H \times W$  grid of  $C$ -dimensional vectors

Outer product of two  $C$ -dimensional vectors gives  $C \times C$  matrix measuring co-occurrence

Average over all  $HW$  pairs of vectors, giving **Gram matrix** of shape  $C \times C$

Efficient to compute; reshape features from

$C \times H \times W$  to  $=C \times HW$

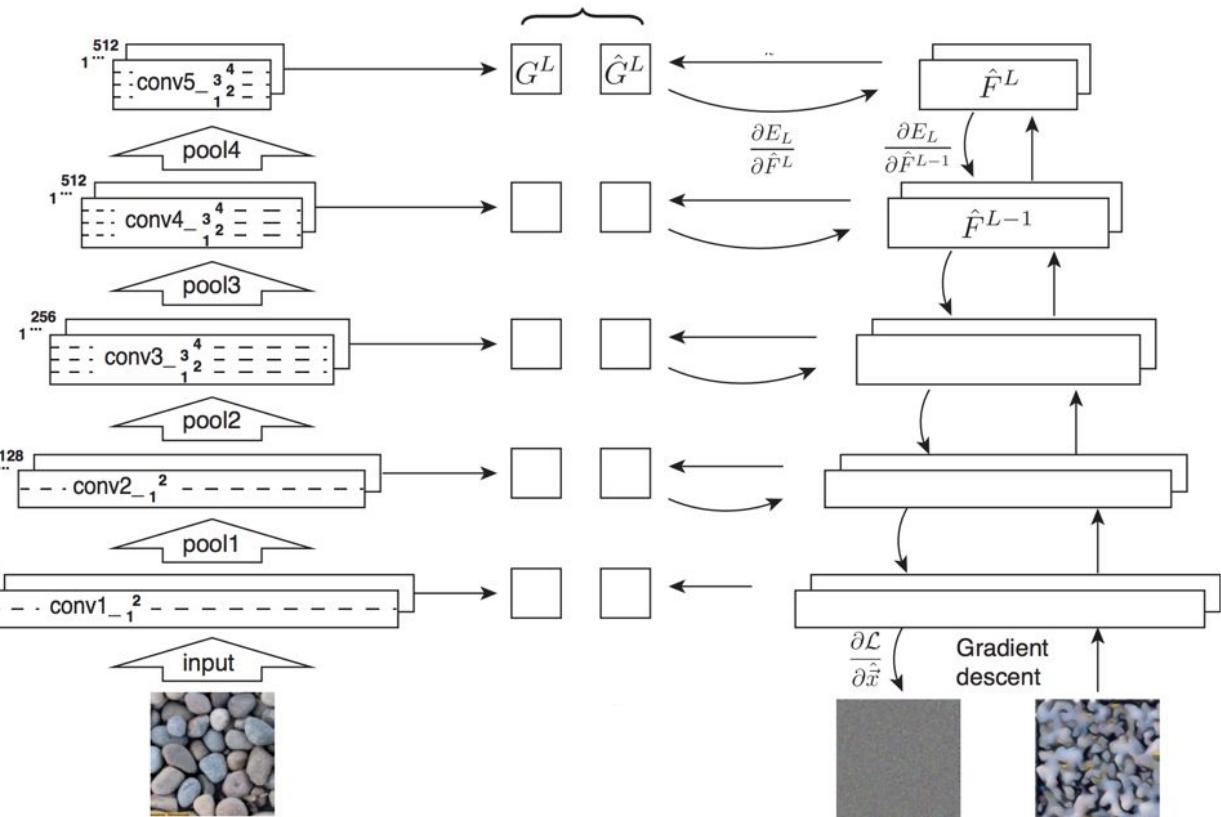

then compute  $G = FF^T$

# Neural Texture Synthesis

1. Pretrain a CNN on ImageNet (VGG-19)
2. Run input texture forward through CNN, record activations on every layer; layer  $i$  gives feature map of shape  $C_i \times H_i \times W_i$
3. At each layer compute the *Gram matrix* giving outer product of features:
$$G_{ij}^l = \sum_k F_{ik}^l F_{jk}^l \text{ (shape } C_i \times C_i\text{)}$$
4. Initialize generated image from random noise
5. Pass generated image through CNN, compute Gram matrix on each layer
6. Compute loss: weighted sum of L2 distance between Gram matrices
7. Backprop to get gradient on image
8. Make gradient step on image
9. GOTO 5

reconstruction)

# Feature Inversion

Given a CNN feature vector for an image, find a new image that:

- Matches the given feature vector
- “looks natural” (image prior regularization)

$$\mathbf{x}^* = \underset{\mathbf{x} \in \mathbb{R}^{H \times W \times C}}{\operatorname{argmin}} \ell(\Phi(\mathbf{x}), \Phi_0) + \lambda \mathcal{R}(\mathbf{x})$$

Given feature vector

Features of new image

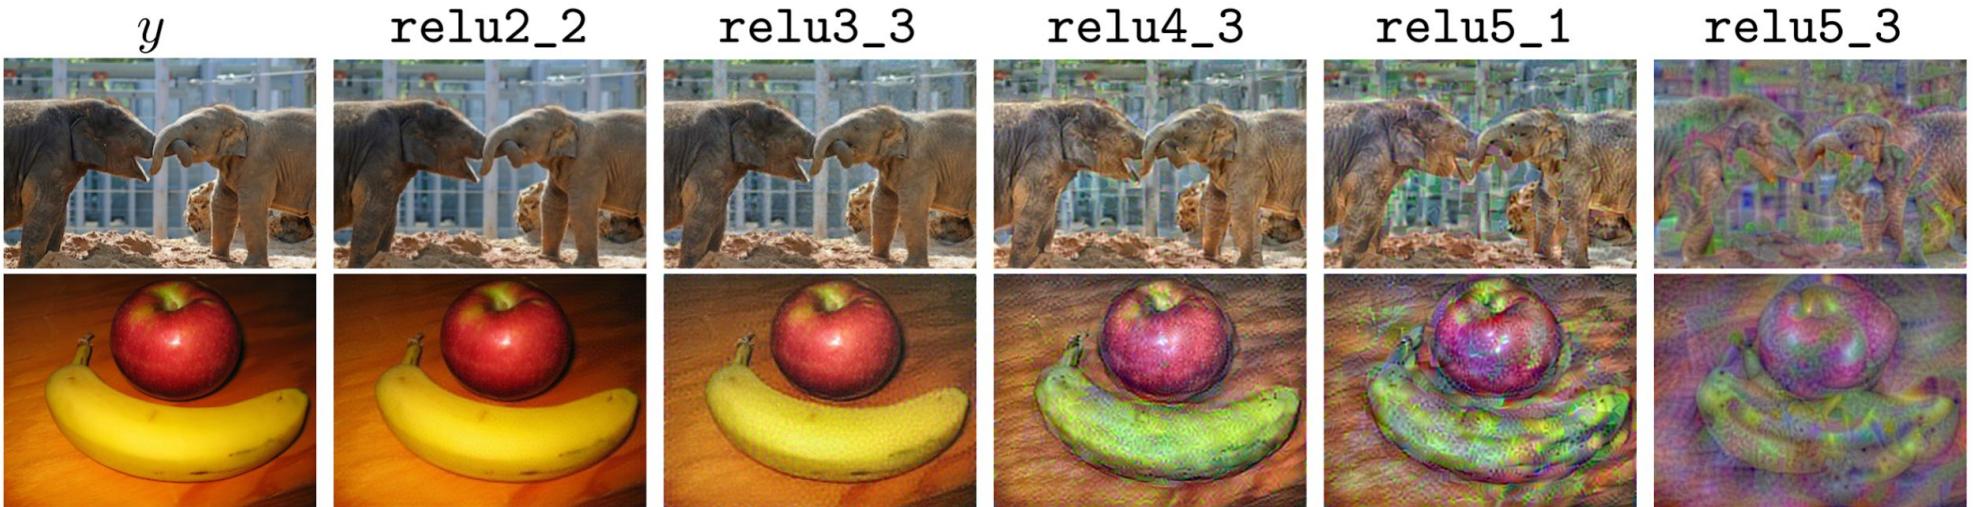

$$\ell(\Phi(\mathbf{x}), \Phi_0) = \|\Phi(\mathbf{x}) - \Phi_0\|^2$$

$$\mathcal{R}_{V^\beta}(\mathbf{x}) = \sum_{i,j} \left( (x_{i,j+1} - x_{ij})^2 + (x_{i+1,j} - x_{ij})^2 \right)^{\frac{\beta}{2}}$$

Total Variation regularizer  
(encourages spatial smoothness)

# Lottery Ticket Hypothesis for Efficient Subnets in Deep Learning

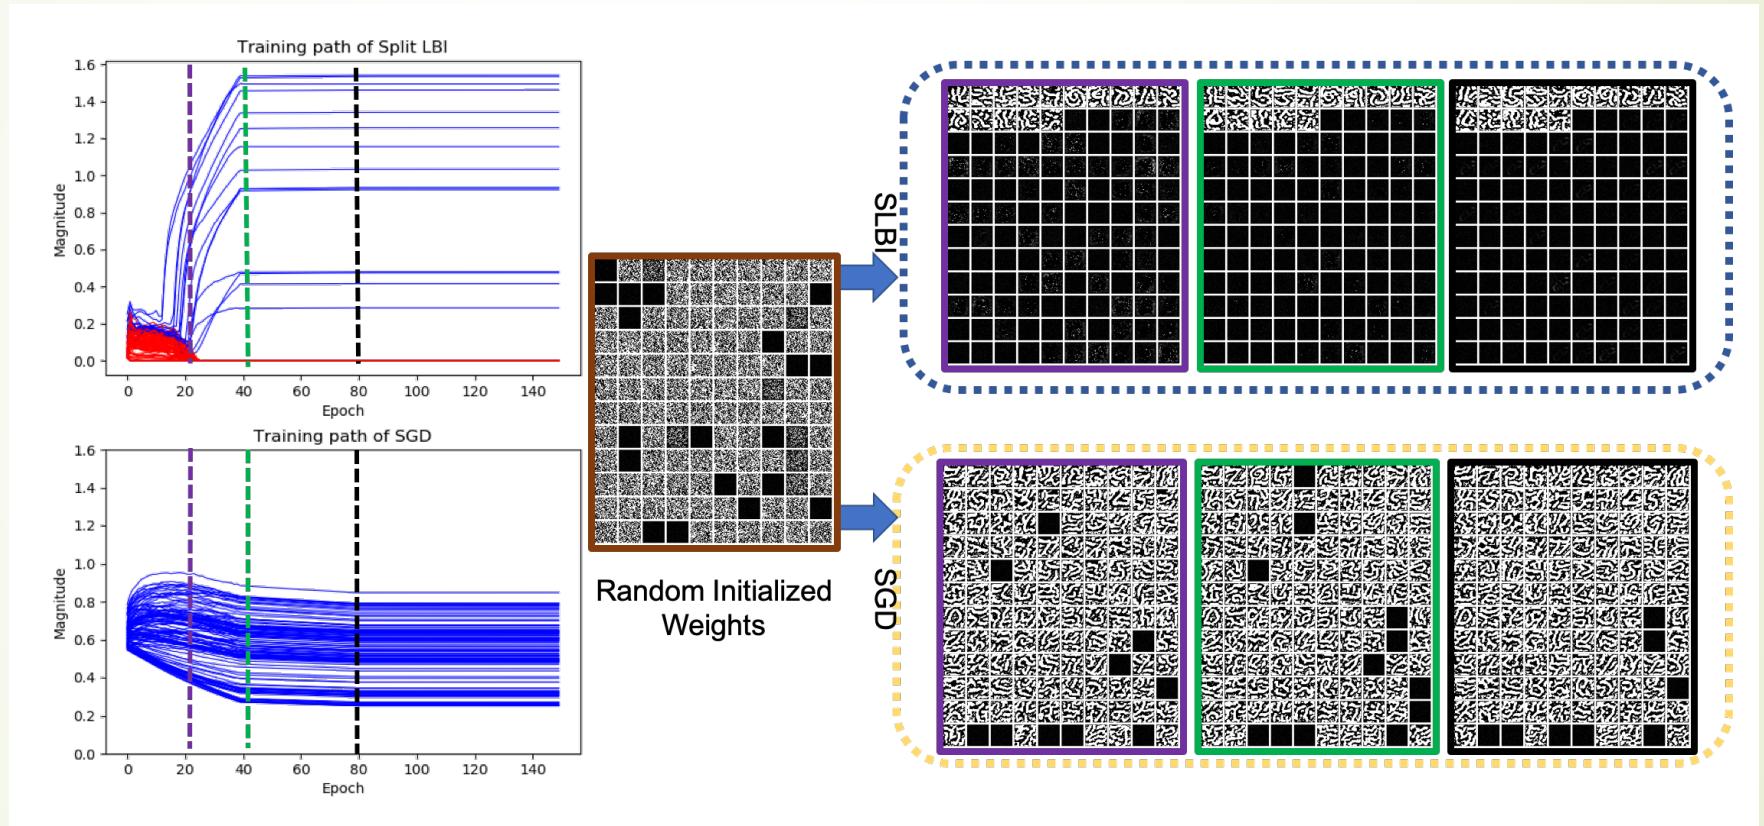

## Lottery Ticket Hypothesis

- *Dense, randomly-initialized, feed-forward networks contain subnetworks (winning tickets) that – when trained in isolation – reach test accuracy comparable to the original network in a similar number of iterations. (Frankle & Carbin, 2019)*

Rewinding the network from the initialization, and find “winning ticket” subnet

# Texture bias in ImageNet training

**Figure:** Visualization of the first convolutional layer filters of ResNet-18 trained on ImageNet-2012, where **texture** features are more important than **colour/shapes**. Given the input image and initial weights visualized in the middle, filter response gradients at 20 (purple), 40 (green), and 60 (black) epochs are visualized. SGD with Momentum (Mom) and Weight Decay (WD), is compared with SLBI.

# Efficient subnets in early stopping

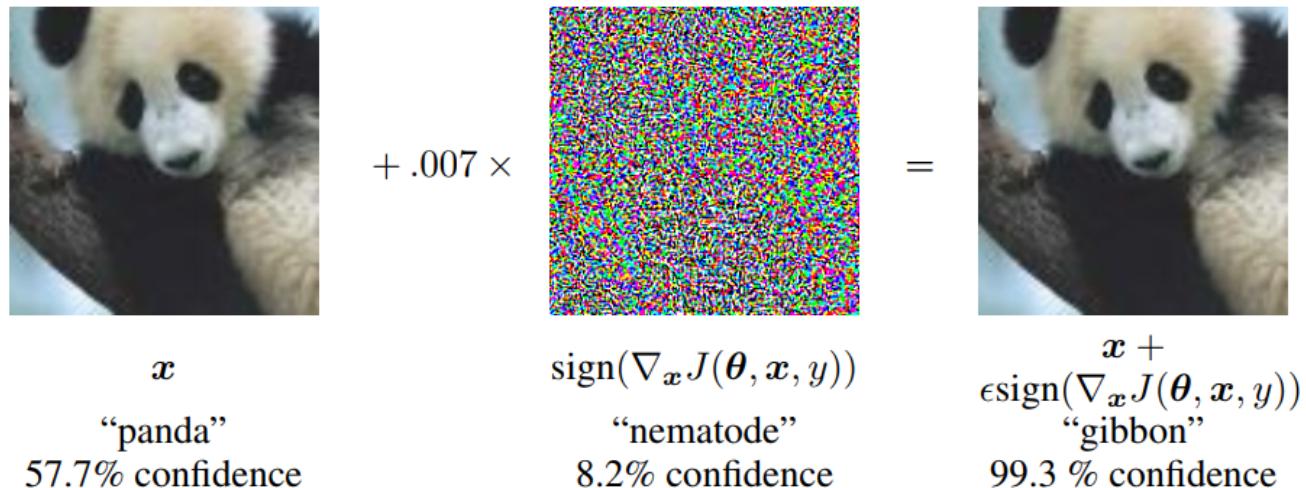

**Figure:** SplitLBI with early stopping finds sparse subnets whose test accuracies (stars) after retrain are comparable or even better than the baselines (Network Slimming, Soft-Filter Pruning, Scratch-B, Scratch-E, and “Rethinking-Lottery” as reported in Rethink the Value of Pruning. Sparse filters of VGG-16 and ResNet-56 are show in (a) and (b), while sparse weights of VGG-16 and ResNet-50 are shown in (c) and (d).

# Adversarial Examples and Robustness

# Deep Learning may be fragile: adversarial examples

[Goodfellow et al., 2014]

- Small but malicious perturbations can result in severe misclassification
- Malicious examples generalize across different architectures
- What is source of instability?
- Can we robustify network?

# Adversarial Examples: Fooling Images

- ▶ Start from an arbitrary image
- ▶ Pick an arbitrary class
- ▶ Modify the image to maximize the class
- ▶ Repeat until network is fooled

# Adversarial Robust Training

- Traditional training:

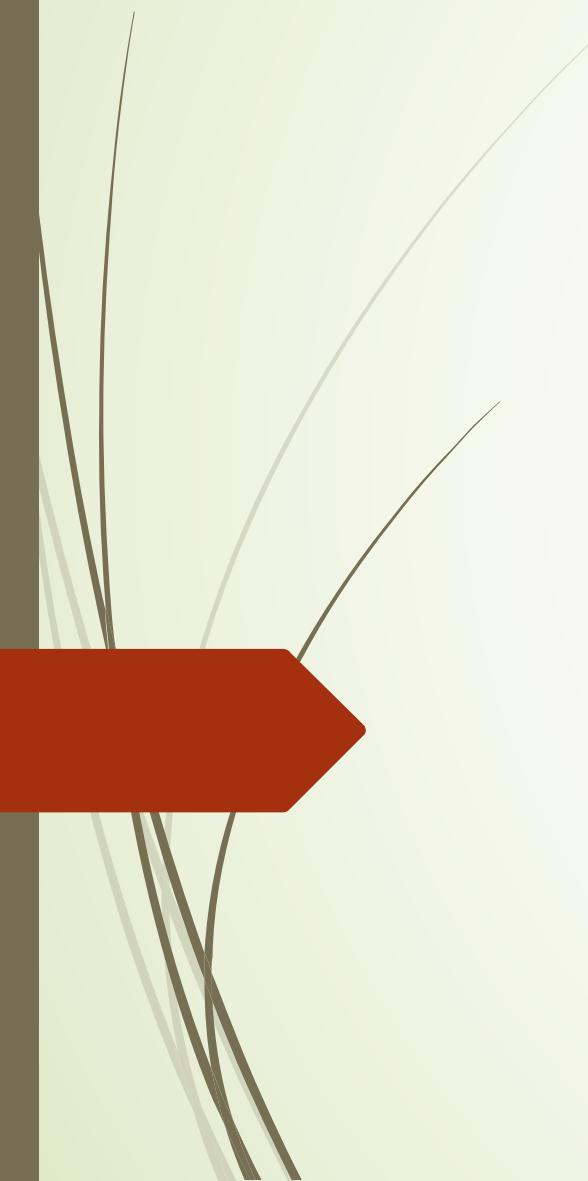

$$\min_{\theta} J_n(\theta, \mathbf{z} = (x_i, y_i)_{i=1}^n)$$

- e.g. square or cross-entropy loss as negative log-likelihood of logit models

- Robust optimization (Madry et al. ICLR'2018):

$$\min_{\theta} \max_{\|\epsilon_i\| \leq \delta} J_n(\theta, \mathbf{z} = (x_i + \epsilon_i, y_i)_{i=1}^n)$$

- robust to any distributions, yet computationally hard

# **Introduction to “(Re-)Imag(in)ing Price Trends”**

By

**Jingwen Jiang**  
University of Chicago

**Bryan Kelly**  
Yale University, AQR Capital Management, and NBER

**Dacheng Xiu**  
University of Chicago Booth School of Business

# Brief Intro

---

In the empirical designs, they first embed 1D time-series data into 2D images depicting price and volumes.

---

Then they feed each training sample into CNN to estimate the probability of a positive subsequent return over short(5-day), medium(20-day), and long (60day) horizons.

---

Afterward, they use CNN-based out-of-sample predictions as signals in several asset pricing analyses.

---

Finally, they attempt to interpret the predictive patterns identified by the CNN.

# Replication task

Mainly focus on:

- ▶ Data Preparation
- ▶ Model Design
- ▶ Workflow Design
- ▶ Performance Evaluation
- ▶ Interpretation

# Data

- ▶ The sample runs from 1993-2019 shows daily opening, high, low prices. The original paper constructs datasets consisting of three scales of horizons (5-day, 20-day, 60-day). Here we just collect the **20-day** version. The total size of data is 8.6G.
- ▶ We already transferred the OHLC charts into images following the same procedures. Current images have the same resolution (64 \* 60) and added with moving average lines(MA) and volume bars(VB).

# Data

- Images labels take value **1** for positive returns ('up') and **0** for non-positive returns ('down'). In addition, we use **2** to mark the NaN value.

# CNN Architecture Design

- ▶ A core building block consists of three operations:
  - ▶ convolution
  - ▶ activation
  - ▶ pooling
- ▶ In the paper, for 20-day images, they build a baseline CNN architecture with 3 conv blocks and connected with a fully connected layer as a classifier head.
- ▶ See the original paper for details (including the selection of the size of the convolution kernel, the selection of the convolution method, the design of the pooling layer and the selection of the activation function, etc.)

# Data Split: Training, Validation, Testing

- ▶ Consider dividing the entire sample into **training**, **validation** and **testing** samples.
- ▶ In the original paper, they use **the first seven-year sample** (1993-1999) to **train** and **validate** the model, in which **70%** of the sample are randomly selected for training and the remaining **30%** for validation. The **remaining twenty years** of data comprise the out-of-sample test dataset.

# Loss and evaluation

- ▶ You can simply treat the prediction analysis as a classification problem. Use Cross Entropy Loss

$$L_{CE}(y, \hat{y}) = -y \log(\hat{y}) - (1 - y) \log(1 - \hat{y})$$

- ▶ To measure the classification accuracy, a true positive (TP) or true negative (TN) occurs when a predicted “up” probability of greater than 50% coincides with a positive realized return and a probability less than 50% coincides with a negative return. False positives and negatives (FP and FN) are the complementary outcomes.

$$\text{Accuracy} = (TP + TN) / (TP + TN + FP + FN)$$

- ▶ For more evaluation metrics or methods, like **Sharpe Ratio**, please refer to the original paper.

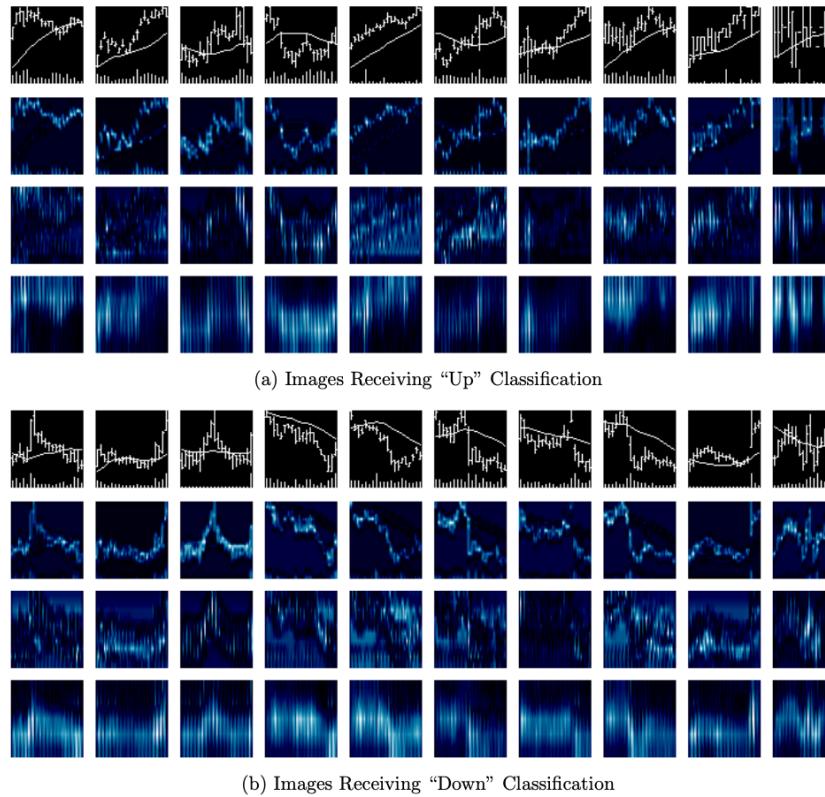

# Training Process

- ▶ The author adopts several ways to combat over-fitting issue and aid efficient computation.
- ▶ They applied the Xavier initialization for weights in each layer, which guarantees faster convergence by scaling the initial weights.
- ▶ Other techniques like applying dropout, using batch normalization and early stopping also assists better performance.
- ❖ We recommend referring to the training details mentioned in the paper 3.3 when training the baseline model.

# Exploring Interpretability

- ▶ Using a visualization method (Grad-CAM) to understand how different image examples activate the regions of the CNN to trigger 'up' or 'down' return predictions.

Figure 12: I20R20 Grad-CAM for 20 Images from 2019

Note: Brighter regions of the heatmap correspond to regions with the higher activation. For each panel, the first row is the original images followed by the grad-CAM for each layer in the CNN.

# Extensions

## ► Ablation studies and test robustness,

- For example, you can perform the sensitivity analysis of the CNN prediction model to alternate choices in model architecture (e.g., varying the number of filters in each layer or varying the number of layers, like the paper shows in Table 18)

Table 18: Sensitivity to Model Structure and Estimation, I20R20

		Loss		Acc.		Correlation		Sharpe Ratio	
		V	T	V	T	Spearman	Pearson	EW	VW

## ► What's more

- ❖ We encourage you not limited to simple binary classification tasks, since the label files we provided consist of more meaningful attributes, containing both categorical and numerical values.
  - For example, you can use the same 20-day horizon images to train your model to predict the return trend of different subsequent y-days even the detailed return values. (y can be 5, 20 even larger).
- ❖ Stock prices might be of high noise, so you may consider other financial markets, e.g. cryptocurrency market
  - For example, Kaggle Contest on G-Research Crypto Forecasting:  
<https://www.kaggle.com/c/g-research-crypto-forecasting>

Thank you!
